The medical profession of the world has the opportunity of showing its gratitude to Rudolph Virchow on his seventieth birthday, October 13, 1891. It may well be said that there is no branch of medical knowledge which has not been made more fruitful through his labors. We appeal, then, with confidence to the physicians of our country, to send forth a tribute which shall represent worthily America's obligations. Contributions will be received by any one of the undersigned physicians:

D. Hayes Agnew, Philadelphia.	Alfred L. Loomis, New York.
Gustav Baumgarten, St. Louis.	William T. Lusk, New York.
William T. Belfield, Chicago.	Henry M. Lyman, Chicago.
John S. Billings, Washington.	William Osler, Baltimore.
H. C. Chapman, Philadelphia.	Wm. Pepper, Philadelphia.
Francis Delafield, New York.	George Ross, Montreal.
Wm. H. Draper, New York.	Nicholas Senn, Milwaukee.
Reginald H. Fitz, Boston.	Fred. C. Shattuck, Boston.
James E. Graham, Toronto.	J. Collins Warren, Boston.
Abraham Jacobi, New York.	Wm. H. Welch, Baltimore.

James T. Whittaker, Cincinnati.

State Care of the Insane.—A public meeting under the auspices of the State Charities Aid Association, was held on May 1st, at Chickering Hall, to commemorate the removal of over 2,000 insane persons from the poorhouses of the State, and the completion of legislation in their behalf whereby, after a contest of four years' duration, the poorhouse system of caring for the insane has been abolished, and the State assumes henceforth the entire charge and maintenance of her dependent insane. Among the speakers were Ex President Grover Cleveland, Bishop Henry C. Potter, and Joseph H. Choate, Esq.

German Congresses.—The Ophthalmological Congress will be held this year at Heidelberg, from September 13th to 17th. The Congress of the German Anthropological Society will meet at Dantzic, in August. Professor Bardeleben, of Berlin, has been elected President of the German Surgical Congress for 1892.

Society Reports.

American Medical Association.

FORTY-SECOND ANNUAL MEETING.

Held in Washington, D. C., Tuesday, Wednesday, Thursday, and Friday, May 5, 6, 7, *and* 8, 1891.

(By Telegraph to the MEDICAL RECORD.)

FIRST DAY, TUESDAY, MAY 5TH—GENERAL SESSION.

THE first general session of the American Medical Association was held in Albaugh's Opera House, the meeting being called to order by DR. D. C. PATTERSON, Chairman of the Committee of Arrangements, at 10.30 A.M.

After prayer by the REV. DR. S. M. NEWMAN, pastor of the First Congregational Church, the Chairman introduced the HON. JOHN W. ROSS, one of the Commissioners of the District of Columbia, who delivered an

Address of Welcome.—Mr. Ross said that he was honored in having been called upon to welcome to Washington a medical society such as this one, the like of which was to be found in no other land. The membership of the Association was recruited from an entire continent, representing almost every possible variety of climate and of conditions affecting the health of the human race, and from this fact it resulted that the accumulated experience of all the associates was more valuable, from its scope and variety, than that of any other national organization in the world.

Professional Secrecy.—One of the important objects of a society such as this was the securing of necessary legislation on medical matters. It was a curious fact that the sacredness of the relation between counsel and client was recognized in common law, and the counsel's lips were sealed as to all matters learned by him from his client; yet there was no recognition in common law of the corresponding relation between physician and patient Many of the States had enacted such laws, but in the District of Columbia the common law prevailed, and the speaker suggested that Congress be asked to pass an act whereby the veil of secrecy might be drawn over the confidences of the patient with his medical adviser.

The Hippocratic Oath was sublime in its high conceptions of the work and moral character of the physician, and the modern Christian physician should exceed these conceptions of the Pagan moralist; he should be the highest exemplar of the honorable man, and he is this and more—he is, by his courage, his sympathy, and other noble traits, an exemplar of the highest Christian morality.

Washington the Permanent Home of the Association.—In no city in this country could an American feel so at home as in Washington, where he felt that he was part owner of the Capitol, the parks, and the public buildings that grace the city. There was no other place where American physicians could meet and feel that they had so well the right to meet, and he hoped that the Association would make Washington its permanent place of meeting.

The ex-presidents of the Association were then invited to seats on the platform, after which Dr. Patterson welcomed the members in a few well-chosen words, and then introduced the President of the Association, Dr. W. T. Briggs, of Nashville, Tenn.

The President's Address.—DR. BRIGGS said that medicine was the true connecting link between science and philanthrophy, and that the gentlemen here present were assembled for the sole purpose of promoting science and the good of humanity. In this age, which is preeminently that of progress, medical science has been no laggard, but has kept pace with, if it has not actually outstripped, all the other sciences. The need that was felt for the co-operation and associated action of all the physicians of the country was what had led to the formation of this Association. A few of those present at the organization of the society were still left, and pre-eminent among them all was the venerated father of the Association, Dr. N. S. Davis.

The Unification of the Profession is one thing that has been accomplished by the Association, for it has established an *esprit de corps* through the Code of Medical Ethics. This latter is the written law of the American medical profession, which holds sway and compels obedience from ocean to ocean, which has elevated this profession in public estimation, and which is the great barrier between the sheep and the goats. Every physician should make this Code the talisman of his life, and every honorable man should be willing to be guided by its every article. Yet there were many men, some of them among the most distinguished of the American medical profession, who had a great repugnance to some of the provisions of this Code, and who had repudiated its authority. Can they affirm, he asked, that their motives for such action were pure and unselfish? Everything possible should be done to lead these men to bury their prejudices and to come back into the fold.

Medical Education.—One of the chief objects of the organizers of the Association was the improvement of the means for medical study in this country, and the elevation of the standard of medical education. A committee for the promotion of this object was early formed, and worked hard and faithfully for many years with seemingly indifferent success. Yet there has been a gradual improvement all through these years, the good seed was sown which was now beginning to fructify. At the present day the facilities for medical instruction in our country were equal to any to be found elsewhere, and the graduates of our medical schools were the peers of medical men in other lands, excelling all others, indeed, in surgery, as the leaders of the profession in Germany and elsewhere had freely testified.

A Qualification for Membership in the Association.—It was undoubtedly due to the efforts of this body that medical education in this country was where it now was, and now that the medical colleges of the land were ready to adopt the suggestions of the college association made last year in Nashville, Dr. Briggs thought that it would be eminently proper to refuse the privilege of membership to all who should hereafter be graduated from, or be professors in, colleges not coming up to the standard.

More Science and Less Business.—The President then spoke of the amount of time consumed in the routine business at the general meetings of the Association. This business is shaped, as a rule, by a few members only, and he suggested that all such matters be referred without discussion to a committee of two members from each State, and that this committee should deliberate upon the questions and report back their conclusions to the general body for approval and ratification. In the meanwhile, the time of the general sessions could be devoted to the discussion and consideration of living scientific questions, by men appointed for this purpose at the preceding annual meeting.

Section of Original Research.—He thought that it would be wise to bring forward again the question of prize essays, which had been allowed to lapse. This would stimulate original research, to which, it must be confessed, American physicians have not devoted as much time as could be desired. We have labored under the possible disadvantage of not being able to obtain government aid, such as is given to workers in other lands, and it was all the more necessary therefore, that private enterprise exert itself to promote the prosecution of scientific investigation. As a step in that direction he would suggest the formation of a section for original research.

An Editor with a Salary.—DR. BRIGGS then spoke of the usefulness of the *Journal* of the Association, and of its superiority over the volume of transactions formerly issued; but it must be admitted, he said, that it has never

come up to the ideal standard of excellence that such a publication ought to maintain. In order to attain this excellence money was needed, and he thought that at least $75,000 or $100,000 should be raised in order to provide a sufficient income. Next to the question of finance was that of editorial management. The editor should be a learned physician and one experienced in editorial work, who could devote his entire time and attention to the paper. He should have absolute control of the *Journal*, and should be empowered to spend money liberally in order to secure the most valuable contributions to medical literature from all sources. To such an editor an annual salary of not less than $10,000 to $15,000 should be paid. Every member of the organization ought, in the words of General Jackson, to "swear by the Eternal" that the *Journal of the American Medical Association* shall be equal to any similar periodical published anywhere in the world.

On motion of Dr. Culbertson, of Ohio, a vote of thanks was extended to the President, and a committee was appointed to consider the suggestions made in the address and to report thereon at the final session on Friday.

The Secretary then read invitations for the members to visit the Government Hospital for the Insane and the grounds of the Jockey Club.

The Report of the Trustees of the Journal was then read. The trustees had recommended that the publication office of the *Journal* be removed from Chicago to Washington, but had thought best to ask the members to express their opinions on the matter through the columns of that paper. These opinions had been so overwhelmingly in favor of keeping the office where it is, that the trustees had acquiesced and would recommend no change. The discussion had brought out expressions of bitter sectional antagonism, which was to be deprecated; yet it had resulted in good to the *Journal*, and in reawakening the interest of the members, which had begun to grow cool.

To Change the Day of Meeting.—Dr. Gihon, of the U. S. Navy, brought up the amendment to the constitution changing the day of meeting to the first Wednesday in May or June, instead of the first Tuesday as at present. He thought that such a change would give more time to members to register and so become entitled to vote at the first general session, and would also allow of time before the assembling of the Association for meetings of various other medical societies. On motion, action upon this amendment was postponed to the next general session.

Rush Monument Committee.—Dr. Gihon then read the report of this Committee. He reported progress—very slow progress—so slow, indeed, that instead of the seven years that the Committee had been at work, seventy times seven would be needed before Dr. Rush's memory could be perpetuated in imperishable bronze.

Philadelphia was not Liberal.—The speaker said that the Committee had resolved to send "coin cards" to physicians, so that each one could send by mail a fifty-cent piece. One of these "coin-cards" with a stamped and addressed envelope had been sent to each of some seventeen hundred physicians in Philadelphia, and enclosed was a letter setting forth the object of the appeal, saying that the trial of this new method was made in Philadelphia since that was the home of Benjamin Rush; that upon the success of this final appeal would be based the decision of the Committee to approach other members of the profession in the same way, and begging each one to send a check, a dollar bill, a fifty-cent piece, or a reply that he did not care to contribute. As a stamped and addressed envelope was enclosed, it was confidently hoped that answers would be received from all, but to the 1,700 letters sent there were but 160 replies. The cost of postage, coin-cards, folding, and addressing was $95, and the amount received was $155.50. The Committee was disappointed in Philadelphia.

The Report of the Treasurer showed a balance in the treasury of $9,427.21.

Wanted: Some Dermatologists.—Dr. L. D. Bulkley, of New York, Chairman of the Section in Dermatology and Syphilography, said that he had been working for four years to organize the Section, but hitherto there had been no attendance. This year he could not find his secretary, had been able to secure but two papers, did not know where to look for members of the Section, and thought they had better give it up. It was moved, later, that two members of each of the living sections be appointed a committee to reorganize the Section on Dermatology, and to improve the other sections.

A Secretary of Public Health.—Dr. Comegys, of Cincinnati, moved for the appointment of a committee to consider the advisability of presenting a petition to the next Congress for the creation of a new executive department of public health, the chief of which should be a cabinet officer.

A Continental American Medical Congress.—Dr. Reed, of Ohio, moved that an invitation be extended to the medical profession of the Western Hemisphere to take part in a Pan-American Medical Congress to be held in the United States, and that a committee be appointed to consider the matter.

A Medical Temperance Society.—Dr. N. S. Davis, of Illinois, announced that there would be a meeting of physicians interested in the subject to establish a national medical temperance society after the model of the British society which had been organized to promote abstinence from alcoholic beverages.

Stenographic Reports of Section Work.—On motion of Dr. Reynolds, of Kentucky, the supervising editor of the *Journal* was instructed to secure stenographers to take verbatim reports of the proceedings of the different sections.

A recess of fifteen minutes was then taken to allow the delegates from the different States to appoint members of the nominating committee. After the reading of the names of this committee and the announcement of the place and time for its meeting, the session was declared adjourned.

Second Day, Wednesday, May 6th.

The session was called to order by Dr. Patterson. The prayer was made by the Rev. Father Richards, President of the Georgetown University.

Address in Medicine.—Dr. E. L. Shirley, of Detroit, Mich., then delivered the annual address on general medicine. He would confine himself, he said, to a consideration of micro-organisms and toxines, and to the diseases associated with them—the infectious diseases—but owing to the limited time at his disposal he would venture a few remarks only of a very general character. Unfortunately as yet we cannot speak with absolute certainty of the nature of the relation existing between micro-organisms and disease, for the two bases affording the support for our argument, namely, laboratory experiments, and clinical observation, are not always in accord, but rather at times seem even to be contradictory.

The Difference Between Life and Death is only a molecular one, and, as has been well said, "I change but I cannot die." The speaker then read an exhaustive catalogue of all the numerous substances entering into the composition of the human body, and of many of the products of vital processes which had been isolated in the different secretions and excretions. Some of these products are exceedingly noxious to the animal organism, being capable, when present in even minute quantities, of exerting a very deleterious if not fatal action upon the vital processes. It is no wonder, therefore, that the equilibrium of health is often upset with such apparent ease, and by such seemingly trivial causes. The changes which we find are those of metabolism and cell-proliferation. Some have asserted that biological are not distinct from chemical processes, but this view is incorrect, for though they are similar we are forced to recognize a certain dif-

ference between them. All the tissues are not equally liable to change from external influences, but possess a varying degree of resistance, varying not only between the tissues of different structure, but in the same tissues at different times.

How Changes Occur.—As yet very little is known positively of animal chemistry, but we know indeed that electrical energy is capable of exerting a marked effect upon living tissue. It is undeniable also that the influence of the vaso motor system over the composition of the blood and over nutrition is potent, for this is proven conclusively by both experiments and clinical facts. Protoplasm, the basis of life, the main substance of cells, is a complex substance that is capable of undergoing great changes, many of which are as yet but imperfectly understood.

Many so-called inflammations are really blood diseases, and by no means local affections. Absorption of ptomaïnes from the intestinal canal is perhaps the true cause of certain pyrexias which are sometimes miscalled malarial troubles.

The question of fermentation caused by the action of microbes is still an unsettled one, but it is certain that these minute organisms are the cause in some way of the elaboration of many toxic substances. The author then related certain experiments which he had conducted, which proved that tubercle-toxine was antagonistic to protoplasm.

Bacteria or their products cause certain diseases, the zymotic diseases, but it is a question whether they do so by their local growth, the action of their secretions, or by inducing certain chemical changes of a destructive character. Yet the mere presence of the pathogenic microorganisms will not cause disease, for most microbes are destroyed by healthy tissues. There must first be some local change by which there is formed a favorable nidus for the growth and development of the micro-organisms. Tubercle bacilli are almost always present, yet we do not all suffer from tuberculosis. The pathogenic bacteria develop only when they light upon a soil which is suitable for them, and then they give rise to the production of certain toxines which act as a poison to the animal organism. Their etiological rôle is a mediate and not an immediate one.

The Therapeutic Indication afforded by this theory of the causation of zymotic disease is an evident one—it is to destroy the bacteria and to neutralize their action. The toxic effect of the tubercle bacillus can be neutralized by certain chemical substances, and it is along this line, Dr. Shirley thought, that the treatment of diseases of this class must be carried out. There seems to be a sort of antagonism between the animal and the chemical poisons, and the speaker believed that the time would come when we could neutralize the animal poisons within the organism without prejudice to the life of the individual.

The Hypodermic Method is the Best for the administration of remedies for this purpose, since there can be no certainty of the action of drugs introduced by the mouth and subjected to the influence of the various secretions of the digestive tract. The speaker desired to awaken in the minds of medical men a greater interest in physiological and pathological chemistry, for in this way only could the art of therapeutics be released from the prison of empiricism.

The speaker delivered his address in a rather low tone of voice, and as there was considerable noise in the hall, he was only indistinctly heard by many of the large audience present.

The address was referred without debate to the Committee on Publication.

The Report of the Librarian was then presented. The necessity of more ample accommodations for the library was dwelt upon.

Some Dermatologists Found.—It was announced that the Section on Dermatology would hold a meeting in the afternoon, two papers and two discussions having been promised.

Owing to the absence of the chairman there was no report from the Committee on Dietetics.

The vote on the amendment to the Constitution which had been made the special order for this morning was then called. Dr. Gihon said that he had tried to express himself clearly in his remarks made when the amendment was introduced, but from the criticisms upon it which he had heard made, it seemed that he had not been understood. It had been said that it was not always possible to express one's thoughts with absolute definiteness in the English language, and perhaps he would have done better had he written his speech in Chinese. He said that he had had no thought of sacrificing the American Medical Association in the interests of the American Academy of Medicine and other societies which some loyal delegates had designated as "side shows;" his object had been chiefly to facilitate the work of the Association and to honor the president, who could then deliver his address to a full audience instead of to the handful that was usually present at the first general meeting.

The amendment was opposed by several members, who feared the change would work injury to the Association. They did not favor the special societies which were getting into the habit of meeting at the same place, and in the same week, as the national society. If these organizations wanted to meet with the American Medical Association let them annihilate themselves, break up their independent organization, and become sections of the main society, which had been compared to an old hen gathering her brood under her wings. This would be a means to promote the unification of the American medical profession, whereas the other plan which seemed to be gaining favor would tend to disrupt it.

A motion was then made and carried to table the amendment.

To Abolish the Committee on State Medicine.—Dr. X. C. Scott, of Ohio, introduced an amendment to the by-laws providing that the Committee on State Medicine be abolished, inasmuch as the Section on State Medicine occupies the same ground. This was amended to read that the nomination of the Committee on State Medicine be taken away from the Nominating Committee and be put into the hands of the Section on State Medicine, and was then carried.

To Establish State and District Branches of the Association.—Dr. J. C. Culbertson, of Ohio, introduced an amendment to the effect that the State and Geographical District Societies in affiliation at this time with the Association, having a membership of one hundred or more, shall be recognized as branches of the American Medical Association, and that all members of said Societies enjoy all the rights and privileges now accorded to delegates.

It was moved and carried that this question be referred to a committee of five to confer with the societies concerned as to the desirability and practicability of the measure proposed.

To Give Permanent Members the Right of Delegates.—Dr. William H. Daly, of Pennsylvania, offered an amendment conferring upon permanent members all the rights and privileges of delegates. This amendment shared the fate of the one proposed by Dr. Gihon, and was promptly laid on the table.

Railway Surgeons.—A communication was then read from the Medical Society of West Virginia, asking for counsel in regard to the treatment by the body of the profession of surgeons in the employ of railways, and for a decision of the question as to how far their conduct was in conflict with the Code of Ethics. It was claimed that railway surgeons give their services to rich corporations, taking passes in lieu of fees or other emolument, a proceeding derogatory to the dignity of the profession, and also that they always assumed entire and sole charge of every case of railway injury, to the prejudice of the family physician or other attendant who may have been first called. The communication also directed attention to the fact of a contract being made between the

railway company and the surgeon, asking why it was not equally permissible to make a contract for medical attendance with private families or individuals.

It was moved to refer this communication to a committee composed of one member from each State, which should consider the points raised therein and report at the meeting of the Association in 1892. An amendment to this motion was made to the effect that the committee should be composed of two members from each State, one of whom should be a railway surgeon. The amendment was voted down, and the original motion then passed.

Dr. Gihon moved that hereafter the president's address should be delivered at the second general session instead of the first, in order that more members might be present to hear it. The motion was laid on the table.

The session was then adjourned.

Third Day, Thursday, May 7th.

The session was opened with a prayer by the Rev. Dr. Bartlett. The Report of the Board of Trustees was then read by the Secretary.

The Journal of the Association.—The trustees reported that the weekly circulation of the *Journal* was a little over 5,400 copies. No editor had yet been appointed. The place of publication would remain in Chicago, and the trustees advised that a building for the permanent home of the *Journal* be erected as soon as there was enough money in the treasury.

The Report of the Nominating Committee was then read. *President*, H. O. Marcy, of Boston; *First Vice-Presiaent*, Willis P. King, of Missouri; *Second Vice Presiaent*, Henry Palmer, of Wisconsin; *Third Vice-President*, W. E. Davis, of Alabama; *Fourth Vice-President*, W. E. Taylor, of California; *Secretary*, William B. Atkinson, of Philadelphia; *Treasurer*, Richard J. Dunglison, of Philadelphia; *Librarian*, George W. Webster, of Chicago; *Trustees*, W. W. Dawson, of Cincinnati, W. W. Potter, of Buffalo, and J. H. Rauch, of Illinois.

Next Place of Meeting.—Hot Springs, Ark., was recommended as the place of meeting on the first Tuesday in May, 1892.

Dr. Cain, of Tennessee, was chosen to deliver the Address on General Medicine. Dr. Hamilton, of the U. S. Marine Hospital Service, on Surgery, and Dr. Lindsley, of Connecticut, on State Medicine.

It was moved to amend the report to change the place of meeting to Detroit. This was opposed by some who stated that the hotels in Detroit were insufficient to accommodate as many members as were present this year in Washington, and also that there was no invitation from the Detroit or Michigan societies. Another amendment was offered, substituting San Francisco in place of Detroit. This was laid on the table. The motion to meet in Detroit was then carried after a rather excited discussion, and the putting and tabling of a number of motions, cries of "We don't want the New York fight over again," cat-calls, shouts of "Question," etc. The report of the committee was adopted on motion of Dr. Davis. The question of Dr. Potter's ethical standing was referred to the Judicial Council. It was then decided that the next meeting be held on the first Tuesday in June instead of May.

The Address on Surgery.—The address on surgery was then delivered by Dr. Joseph M. Matthews, of Louisville, Ky. The speaker said that he had been embarrassed in selecting a theme for his address, but had finally taken the subject of stricture of the rectum. He doubted whether spasm of the rectum was ever seen, and if it were it would be symptomatic only. Dysentery as a cause of stricture he rejected, looking upon it rather as a consequence of stricture. Tuberculosis is an occasion of ulceration but not of stricture. The grand common cause of stricture is inflammation, but this is a very general term, including traumatism, cancer, and syphilis. The only venereal cause is secondary syphilis, the prime, the sole etiological factor is inflammation.

The speaker objected to colotomy, believing that it was often done uselessly, when there was no possible chance of relieving the patient. He looked upon this operation as a dernier ressort, and deprecated its performance early in the progress of the disease. We cannot always diagnose cancer in its early stages, and the making of an artificial anus for benign stricture is never justifiable. The operation, furthermore, does not prolong life, nor does it, as a rule, relieve the pain in the rectum. Pain is not always present, and when it is it can be overcome by opium. When a patient has only a few years to live there can be no serious danger of his becoming addicted to opium. Obstruction can usually be overcome by dilatation, so that colotomy is not indicated by this condition. From twenty to forty-five per cent. of all operations of colotomy result fatally within twenty-one days, and those patients who survive are benefited in no measure proportionate to the risk of the operation and the distress caused by an artificial anus. The diagnosis of stricture when within four inches of the anus is easy, but it is often difficult to determine its character.

Dr. Matthews believed that at least sixty per cent. of all cases were due to syphilis, and most of the rest were malignant. The induration of syphilis is more even than that of cancer. The speaker condemned utterly the use of bougies, either of metal or hard rubber, in the diagnosis of stricture, on account of the great danger of the procedure.

Treatment of Stricture.—He objected to gradual dilatation and looked upon forcible divulsion as the most useful in cases of fibrous stricture. He was very partial to incisions, more especially internal division, and did not believe there was much risk in the latter. There is no necessity of passing bougies subsequent to the operation, when linear incisions will accomplish so much at one sitting.

Dr. Matthews did not see the use of resorting to such a tedious method as electrolysis, even were that operation effectual. He did not, believe in extirpation for benign cancer, but it was the ideal operation for cancer when seated low enough in the rectum. Excision removes the disease and gives the patient a chance of cure, whereas the horrible and disgusting operation of colotomy is at the best only a palliative. It does not relieve pain, does not cure the patient, does not prolong life, and is no more effectual than other means in obviating the effects of obstruction. Colotomy might be justifiable in the case of cancer of the sigmoid flexure, and of fibrous stricture high up, where it cannot be divulsed, incised, or extirpated. In the case of non-malignant stricture high up the operation will prolong life and relieve suffering, but for low stricture, whether benign or malignant, it is never indicated. Where colotomy is to be performed, the lumbar operation is preferable.

The address was well received, and was referred without discussion to the Committee on Publication.

On motion a committee was appointed to consider the advantages of creating a Section on Benevolence, looking to the relief of the widows and orphans of deceased members.

After the transaction of some further general business the session was adjourned.

Association Notes.

The Tin Badge has been suppressed this year, and the delegates are no longer labelled like a band of marksmen or the members of a summer fishing club.

The American Editors had their annual meeting at the Arlington Hotel on Monday evening. The principal business was the election of officers, which resulted as follows: *President*—Dr. Frank Woodbury; *Vice-Presi-*

dent—Dr. C. H. Hughes, of St. Louis; *Secretary*—Dr. C. C. Culbertson, of Cincinnati.

After adopting as a subject for the next meeting's consideration. "The Best Interest of the Medical Journal from a Literary Standpoint," the association adjourned to Chamberlain's to enjoy the annual dinner.

A Season of Meetings.—The meeting of the Association has been made the occasion of drawing the members of many other societies to Washington Among the associations which have been deliberating in the capital city are the Association of Insane Asylum Superintendents, the American Association of American Editors, the American Academy of Medicine, the Rocky Mountain Medical Society, the National Conference of State Boards of Health, and possibly others. There are to be at least two new organizations effected, namely, the American Medical Temperance Society and the Association of State Medical Examiners.

Receptions.—A reception to the delegates and their families was given by the physicians of Washington on Tuesday evening, at the Arlington Hotel. On Wednesday afternoon the members were received by Secretary Blaine at the State Department, Secretary Proctor at the War Department, and Secretary Foster at the Treasury. Wednesday evening a reception was given by Dr. Hammond. The delegates were also invited to Mr. Waggaman's private art gallery and to the Corcoran Art Gallery. Thursday night the Surgeon-General received at the Army Medical Museum, from 8 to 10.30, and the Director of the National Museum received at that institution on the same evening. An excursion to Mount Vernon took place on Friday afternoon.

A Good Presiding Officer.—It is generally conceded that Dr. Briggs has been a success as presiding officer of this meeting of the Association. He gave his decisions promptly and fairly, never losing his head, being firm in the assertion of the rights and dignity of the chair, and showing no favor to the oldest and most prominent of the members over the youngest and least known. In a word, he did as well as he knew how, and he did know how.

Dr. E. Carroll Morgan, of Washington, died on Tuesday night. He was a son of the late Dr. James E. Morgan, and was thirty-five years of age at the time of his death. He was born in Washington and was graduated in medicine from the University of Pennsylvania. He afterward went to Europe and studied laryngology in Paris and Vienna. He was a member of the American Medical Association, and was president of the Laryngological Society.

The National Conference of the State Boards of Health.—The seventh annual meeting of the National Conference of the State Boards of Health was held in the Ebbitt House, on the Saturday and Monday before the meeting of the Association. Dr. J. N. McCormack, of Bowling Green, Ky., presided. An address of welcome was made by District Commissioner Douglass, after which Dr. Cochran, of Alabama, read a paper entitled: "What are the Requisites for a Thorough System of Quarantine and Maritime Sanitation, in the Light of Present Scientific Attainment?" He thought that the port of Havana was the proper place for quarantining yellow fever ships, which nearly all came from Cuba. Next Dr. S. R. Olliphant, of New Orleans, discussed the questions: "Given a vessel, with cargo, from Central or South America or the West India Islands, can such vessel and cargo be disinfected without discharging the cargo?" and "Can such cargo be disinfected thoroughly and without damage after it has been discharged?" The speaker believed that the best method of disinfection of vessels was by sulphurous acid. Dr. Cochran did not think disinfection of a ship's hold and cargo could be effected in this way. Dr. Salomon, of New Orleans, read a paper on the means of preventing the carrying of infection from one State to another. Dr. Balch then discussed the question: "Should State boards of health have control of the sanitary arrangement of all school buildings to be erected within their boundary?" and, "What is the best plan to secure such control?" He argued against the direct control of school matters by the State board. The second session was occupied mainly with the discussion of what boards of health should teach and do to prevent consumption. The election of officers resulted as follows: *President*—Dr. J. W. McCormack, Kentucky; *Secretary*—Dr. C. O. Probst, Ohio; and *Treasurer*—Dr. Henry B. Baker, Michigan.

Could not Get In.—A number of delegates had selected the Riggs House as their abiding place during the four days of the meeting, and many had written to secure rooms in advance, but when they arrived on Monday they found the hotel closed to guests, and an auction of all the furniture being held.

The Cold Wave visited Washington as well as the rest of the country, and many of the delegates had cause to regret their want of foresight in leaving their overcoats and thick clothing at home.

SECTION ON PRACTICE OF MEDICINE AND PHYSIOLOGY.

VICTOR C. VAUGHAN, M.D., CHAIRMAN.

FIRST DAY, TUESDAY, MAY 5TH.

The Growing Importance of Chemical Studies in Medical Education and in Medical Research—DR. VICTOR C. VAUGHAN, chairman of the Section, in this paper directed attention to the most important problems now being investigated in the line of chemistry.

The Chemistry of the Animal Cell.—With the form and size of the various cells of the animal body in health and disease we were already fairly acquainted, but it should be remembered that these ultimate entities of life had also a physiological and a chemical history. "Upon what do they feed? What is the nature of their secretions and excretions? These and many other questions pertaining to their life-history are worthy of study. The diverse ways in which the various cells of the body and the several parts of the same cell are affected by staining reagents suggest important differences in chemical composition." Miescher and Kossel had shown that certain compounds existed as characteristic constituents of the nuclei. They belonged to the proteids, but differed from other members of this group in that the albumin molecule was not free, but combined with phosphoric acid. This combination was exceedingly loose, decomposition taking place at even the ordinary temperature if the compound were kept moist. It had been called nuclei. It had been supposed that phosphoric acid in the body existed as inorganic salts. This was true of most of that contained in the bones, muscles, and blood, but not of that of the glandular organs. The smaller the proportion of nucleated cells in any tissue, the smaller was the amount of nuclei. The amount of organically combined phosphoric acid was a measure of the nuclear substance in a given tissue, and this could be isolated and weighed, thus giving a more exact estimate than could be obtained by counting the nuclei under a microscope. This procedure could be made serviceable not only in physiological, but also in pathological, work.

Albumin and phosphoric acid were not the only constituents of the nuclei. Nuclei, on being artificially decomposed, furnished certain basic substances, as adenine, guanine, hypoxanthine, and xanthine, which were characterized by the large amount of nitrogen which they contained.

Nuclein did not form a reserve food-supply, as did glycogen, fat, and albumin. Cyanogen bodies had a well-known tendency to transform themselves into substances having a complicated constitution.

With a knowledge of the conditions under which cells multiplied, of the nature of their pabulum, of the manner in which they converted foods into living tissue,

what a great advantage the scientific physician would have over those who to-day had to rely in the treatment of disease upon empiricism. The chemist hoped to acquaint himself with the nature of cell-substance, and be enabled from this knowledge to supply the living cells of the body with proper food, to point out to the practitioner the effects of certain therapeutic agents upon the cells of the liver, and, what would be of equal importance, the action of the cells of the liver upon the therapeutic agents. We knew at present but little of the form in which our medicinal agents reached the diseased organ, and yet, without any knowledge on this essential point we endeavored to effect the nutrition of the various parts of the body. A substance might undergo one or more marked changes in chemical composition during its passage through the body. Examples were given in camphor, etc.

Reference was made also to the investigations of Schröder, going to show that urea was, in part at least, formed in the liver from ammonium carbonate; and to those of Minkowski on the formation of uric acid; to the question of whether kreatin was one of the antecedents of urea; to the influence of impure air upon the chemistry of the living cells. He then passed to the chemistry of the absorption of foods. There seemed to be a popular idea that peptones filtered through the walls of the intestines without let or hindrance. Scientific experiments had shown that this view was quite erroneous. There were many reasons for believing that in health a small part of our proteid food was never converted into peptones, but was fitted for its service to the animal economy during its absorption through the walls of the intestines. The active agents which rendered this portion fit to enter the circulating blood were not the unorganized digestive ferments, but were the living cells of the absorbing mechanism.

The author then gave recent information on the reconversion of fatty acids, set free by the action of the pancreatic juice, into neutral fats while passing into the thoracic duct. From the facts given, it seemed evident that the cells of the absorbing mechanism of the intestines synthesized the fatty acids, and in every case the synthesis consisted in a combination of the acid with glycerine. He then took up the nature of the change whereby peptones were converted into serum-albumin; then the chemistry of the liver, of the nerve-cells, of albumin, and concluded by pointing out the value of chemical research in pathological studies.

Case of Fatty Urine Accompanying an Abscess in the Right Iliac Fossa.—Dr. J. P. Connolly, of Williamsport, Pa., reported the case, which occurred in a colored woman who had been in health until the birth of her child. After that event she had had chills at irregular periods for a long period, but did not call her physician until January, 1890. He found her with symptoms attending elevation of the temperature, which had begun with chill. She also complained of pain in the right iliac region, and palpation revealed a deep-seated tumor with obscure fluctuation. The patient told him that her urine contained fat, and on investigation was found to be covered with an oily substance resembling castor-oil in consistency, but becoming thick like tallow on cooling. Three and a half ounces avoirdupois were passed daily for eight days, and then immediately disappeared after the sudden discharge of a large amount of pus with the urine. Pus continued in the urine about three months. The patient slowly improved, and in five months was apparently well.

The urine had been examined for sugar and albumin, and found to contain none. The patient had not been taking cod-liver oil or other oils. The blood did not contain filaria. A few other cases had been reported. In Cushing's, the fat appeared after the escape of pus, and the patient died.

Digitalis in the First and Second Stages of Pneumonia.—Dr. J. W. Carhart, of Lampasas, Tex., in this paper deprecated the use of digitalis in the first and second stages of pneumonia, having more especially reference to the broncho-pneumonia of children. To this method of treatment he attributed much of the large death-rate given by Ziemssen and other authors.

A clinical picture of the condition present in pneumonia was given, and the physiological action of digitalis briefly stated. It was not necessary to consider whether pneumonia was a systemic disease with a local expression, or a local affection with systemic consequences; we found as a fact the lungs engorged, swollen, and hot, blood stasis, infiltration, obstruction in fine capillaries, lack of aeration of the blood, carbonic acid poisoning. Digitalis exaggerated this state of things by its effect upon the nervous system, and in causing irregular action of the heart. He quoted Dr. Loomis' recommendation of this drug in pneumonia in Pepper's "System of Medicine," who contradicted the claims here made elsewhere.

Tuberculin—Its Value as a Scientific Discovery.—Dr. S. K. Jackson, of Norfolk, read the paper. He thought the evidence went to show that the curative action of tuberculin was due to the fact that it was a product of the germ which caused tuberculosis. He had shown in a paper read in 1879 that a living organism could not exist on its own excreta, and had then and several times since made this fact the basis of some therapeutic suggestions. This might offer an explanation of the action of sulphuretted hydrogen, of alcohol, and other agents which had been found useful in tuberculosis.

Koch's Treatment of Tuberculosis.—Dr. H. D. Geddings, of the Marine Hospital Service, in this paper gave an account of this method of treatment in twelve cases. Apparently cured, two; much improved, one; improved, one; unimproved, two; worse under treatment, four; death, twos. Only one was a case of lupus, which was improved. In three there was laryngeal complication of the lung disease. His conclusions were: 1, That tuberculin is a powerful agent, about which little is yet known, not to be used by the general practitioner; 2, that in a limited number of cases which come under observation in the incipient stage of the disease it is beneficial, provided the disease is not extensive, and that softening and breaking down of tissues has not taken place, or the patient's vital forces have not been exhausted; 3, that its results in tubercle of the larynx are very variable, it is liable to produce most distressing and alarming symptoms; 4, that in cases where softening has taken place, or the patient is exhausted, a fatal issue is hastened; 5, that in hemorrhagic cases the use of tuberculin is prejudicial, producing rapid and violent harm.

Two Additional Cases of Forced Respiration.—Dr. Fell reported the cases and demonstrated the working of the apparatus as he has now perfected it. Altogether seventeen lives had been saved by this method which could not be saved by any of those previously in use. One of his two cases occurred in a medical student, a female, who was suffering extreme morphine narcosis. The bellows was used first with the face mask for three hours, but as the symptoms were becoming more alarming, the pulse could not be felt nor the heart heard, tracheotomy was performed to avoid forcing air into the stomach instead of into the lungs. At this stage the case was considered almost hopeless, but with the tube in the larynx signs of returning life began slowly to make themselves evident, and after fourteen hours the patient could be left to breathe for herself. In the other case the patient had taken repeated doses of phenacetin, morphine, and cocaine in small quantities, until a poisonous amount had been consumed. Here the face mask had also to be given up after some hours for tracheotomy. The patient was considered nearly out of danger after keeping up forced respiration all night, but during the speaker's absence died of heart failure next morning, brought on by vomiting. In this instance he tried oxygen inhalation for the first time. He believed this patient would also

have recovered had morphine alone been taken. He was of the impression that forced inhalation would prove of value in surgical shock.

The Treatment of Chronic Phthisis.—Dr. Asa F. Pattee, of Boston, read a long paper with this title. He thought we were in danger of overlooking well-recognized methods of treatment and prevention in giving so much attention to the part taken by disease germs. He had claimed for many years that tuberculosis could be cured even after extensive destruction of lung-tissue had taken place, provided the patient's constitutional powers had not been exhausted. In 1857 he wrote a thesis on pure air, pure water, cleanliness, and exercise, their importance in the cure of disease. Since that time he had found these agents his best allies, and the present paper consisted largely in showing their practical application in the treatment of consumption. The best germicide was health; the bacillus tuberculosis could not thrive in the healthy lung. To overcome the disease when it had once got a hold it was necessary for both nutrition and exercise to be cumulative. Besides dwelling on the diet, air, exercise, cleanliness, sleep, the author also considered the comparative value of antipyretics and other medicinal agents.

SURGICAL SECTION.

Dr. T. A. McGraw, Chairman.

Use of the Elastic Ligature in the Surgery of the Intestine was the subject of the address of the Chairman. Dr. McGraw referred to the work of Senn as having given the impulse to intestinal surgery and having placed it on a sound pathological basis. He said that the operation for intestinal anastomosis was made for—1, chronic stenosis of the gut; 2, acute obstruction; and 3, some cases of gangrenous hernia, false anus, and fecal fistula. He regarded the dangers which beset the operation as shock from a too prolonged operation, hemorrhage, and the escape of the contents of the gut into the abdominal cavity. To escape from these dangers, and especially to reduce the time of the operation, which by the usual methods was from twenty to thirty minutes, by at least ten or fifteen minutes, he had devised a new operation. It had occurred to him that if a junction could be formed between the opposing surfaces before an opening was made between the two coils of intestine, it would obviate escape of contents and hemorrhage. For this the elastic ligature was adopted. A rubber cord, two millimetres in diameter, was trimmed down at the end so as to enter the eye of a worsted needle, which eye being smaller than the calibre, the rubber cord must needs be stretched to be drawn through. Thus arranged, the cord more than filled the hole made by the needle. The opposing coils of gut having been brought in apposition, the needle is passed through, as near as possible at right angles to surface, and the stitch taken in the line of the long axis of the gut, at a point farthest distant from the mesentery. An inch or more in length is included in the ligature. A square knot is then tied, the ligature being drawn as tight as possible without breaking the cord. The knot is finally fastened by a silk thread passed beneath the knot and tied around it. The ends are cut close.

From the symptoms which arise when a small portion of the gut is pinched in a strangulated hernia it might be expected that like symptoms would arise when the gut is pinched by the constantly contracting ligature. Such, however, has in no instance been the case.

In the experiments made upon dogs, after twenty-four hours no change has been found, except adhesions between the adjacent surfaces, and partial obliteration of the intestinal folds. After forty-eight hours the folds were found to have entirely disappeared, and slight cutting was present at the points of passage of ligature. At the end of seventy-two hours these cuttings were of sufficient size to admit of the passage of water, and the ligature was still hanging in the centre. At four days the ligature had fully cut through, and the wound had a smooth, healed edge. In the first series twenty-four dogs were operated upon. Then the first trial was made upon man. The patient suffered from cancer of the pylorus, and anastomosis was sought between the stomach and the highest coil of small intestine presenting. The operation, after exposure of the stomach, though done with great deliberation, lasted but eleven minutes. (The author now does the operation upon the dog in three minutes.) The patient suffered no irritation of the stomach at any time, and food passed at the end of the fourth day. Diarrhœa, however, soon came on, and the patient died of inanition at the end of two weeks. At the autopsy it was found that the anastomosis with the small intestine had been effected at a point somewhat over three feet from the pylorus—a point too low down for purposes of nutrition.

The anastomosis had been completed with the minimum of irritation. The writer believes that the operation is not applicable to cases demanding relief sooner than four days, but that it has very decided advantages over other forms of the operation in cases of partial stenosis from any of the many causes, and where the patient has a fair degree of strength.

Experiments on dogs to effect anastomosis between the gall-bladder and intestine did not prove satisfactory. In the dog the parts are difficult of access, and the movements of the diaphragm are prejudicial. Bile escaped into the abdominal cavity, while the contents of the intestine never did. Six of the nine dogs experimented upon died; of those living the opening was found to have closed after seventeen days. The openings between the stomach and intestine have also been found to contract in five months to one-half their original size.

On Appendicitis and Pericæcal Inflammation.—Dr. Thomas G. Morton, of Philadelphia, read a paper on the above subject. He pointed out the importance of early diagnosis, prompt operation, and thorough exploration of the abscess-cavity, and he considered it of vital importance to remove the appendix vermiformis if it be found diseased. He reviewed the pathology, and held that the opening into the appendix is not patulous; that the calibre is not as large as a goose-quill, but that ordinarily there is no cavity at all, the walls being collapsed and usually only admitting a probe; that the opening is usually closed with mucus; that in length it is from three to nine inches, and that it is not joined to the cæcum at its lowest point

He divided the cases into three groups: 1. Where irritation or simple inflammation only is present; in these the diagnosis is not easy. 2. Where inflammation of a severer type, with ulceration or perforation, gave tumefaction and other evidences of inflammation. 3. Where ulceration and perforation had occurred without sufficient lymph exudation for protection; in these the onset was sudden, but it was usually not the first attack.

Symptoms.—First group: Pain, increased by pressure, and possibly nausea, vomiting, constipation, and an accelerated pulse. Second group: Tumor from lymph exudation, but with no symptoms of pus formation because of the thick walls. Third group: No encasing wall, all symptoms sudden, and those of intense local and general peritonitis.

Several cases were reported in detail. The author advises removal of the appendix, if possible, in the interval between recurrent attacks.

In the discussion—participated in by Drs. Fenger, of Chicago; Marcy, of Boston; Manley, of New York; Gaston, of Atlanta, Ga.; Murphy, of Minnesota; Davis, of Birmingham, Ala.; Stanton, of Fremont, O.; Tiffany, of Baltimore; Pierman, of Champagne, Ill.; McGray, of Atlanta, Ga.; and Thomas, of Pittsburg, Pa.—all views were held, from the necessity of operations in every case to operation in but one case in twenty.

Dr. McGray stated that in his position of Demonstrator of Anatomy he had found evidences of disease of the appendix in thirty five per cent. of all autopsies from death from whatever cause. This led Dr. Thomas to say that, without operation, death was the exception, recovery the rule.

The Scientific Rationale of Modern Wound Treatment.—Dr. Henry O. Marcy, of Boston, reviewed the experiments of Jeffries Wyman, published in 1867, and the work of Lister. He quoted from the recent paper of White, of Philadelphia, and Tate's reply. He said that to sterilize the surroundings and the materials used, and to restore the parts to their normal state, was the ideal treatment for wounds.

A New Operation for Harelip.—Dr. Christian Fenger, of Chicago, said that in all cases of harelip, single or double, complicated or non-complicated, there was a deficiency in the prolabial tissue—not too much. Most operations remove more or less of this prolabial tissue. The new operation, which he illustrated by diagrams, did not do this. The incision was linear, and he considered it of prime importance that the sutures did not appear on the side of the mucous membrane. Deep tension sutures were first put in, afterward the skin sutures. Sutures were held by artery forceps until all were in, and then all were tied. The part was then dusted with fine powder of boric acid and covered with collodion. Outside, adhesive plaster immobilized the cheeks.

Some Points in the Surgical Treatment of the Radical Cure of Hernia.—Dr. Augustus P. Clarke, of Cambridge, Mass., laid great stress on proper material for sutures. The sutures should be aseptic and the wound should be aseptic. The surgeon should attend to the final preparation of the sutures himself, those sold in the shops were not to be trusted. The best material for buried sutures is animal membrane, catgut or tendon. Silk, as a foreign substance, should never be used; and the same may be said of horse-hair. The several different tissues should be coapted in proper order, and no drainage should be used. The obliquity of the inguinal canal and the relation of the internal and external abdominal rings should be maintained.

SECTION ON OBSTETRICS.

Dr. C. A. L. Reed, of Cincinnati, Chairman.

First Day, Tuesday, May 5th.

The session was opened by The President, who expressed his profound appreciation for the honor conferred on him by his election to this office, which had been filled by so many honorable men, first of whom was Dr. Alfred C. Post, of New York. It was his duty to trace the progress in obstetrics and gynecology, and the first words of his address included one great advance, viz., *Ladies* and Gentlemen. He thought it a matter of very great importance that ladies had been admitted to this Section and to this work. He traced the evolution of the Section from the time when there was only a Committee on Obstetrics, which reported, may be, every two or three years; then obstetrics was added to the Section on Medicine; then obstetrics, gynecology, and pediatrics were grouped together; then pediatrics went by itself, and now, on looking at this immense programme, he would say that there was abundant material for two sections, one on obstetrics and one on gynecology. He then took up specialism in medicine and then special societies. He hoped the transactions of the Section would now appear more exclusively in the *Journal* of the Association, and did not favor their publication promiscuously. He again returned his extreme gratitude for the honor conferred on him by his election as chairman of the Section.

The Prevention of Puerperal Convulsions by the Induction of Premature Delivery was the subject handled ably by Dr. H. D. Fry, of Washington. The Doctor considered the chances of the child better from induced abortion than from living in the poisoned blood of the mother. Of 829 premature children, with an average weight of four pounds, 662 lived. Tarnier, by his system of gavage, saved thirty per cent. of children at the sixth month. The safest, simplest, and best method of inducing abortion is by inserting a bougie between the uterus and the membranes. The catheter is not to be used. It is a dirty, hollow instrument which is not easily kept clean. The bougie should be immersed in a solution of bichloride for twenty-four hours and then washed in boiled water. He does nor advise abortion for simply the presence of albumin, but only when convulsions are threatened.

Dr. Byron Stanton, of Cincinnati, thought that the cases requiring induced labor for the prevention of convulsions were extremely few. The shock of induced labor is too great. If labor has commenced it is our duty to hasten it so as to abbreviate shock. Methods of inducing abortion are so well known as not to justify discussion here. The induction of labor should be deferred as long as possible. The presence of albumin or the presence of convulsions do not necessitate it, unless they cannot be controlled in any other way.

Dr. W. W. Potter, of Buffalo, advocated the early induction of labor in threatened abortion.

Dr. A. F. A. King, of Washington, advocated the postural treatment, viz., the knee-chest.

Spasmodic Stricture of the Urethra Following Labor was the subject of a paper by Dr. Llewellyn Eliot, of Washington. He reported two cases which, from their rarity, he thought of interest to the Association. Both occurred on the seventh day after labor.

Laparotomy, with the report of cases, was the subject of a paper by Dr. J. H. Branham, of Baltimore. His cases amounted to eleven. They were his first and all occurred during the past eighteen months. They were of great interest to him and he made them appear so to his hearers.

Papillomatous Cystoma of the Ovary, with report of a case, was the subject treated by Dr. A. B. Walker, of Canton, O.

A Report of Ten Selected Cases of Laparotomy, with remarks, was the title of a paper read by Dr. J. H. McIntyre, of St. Louis. These ten cases were selected from a large number, and were chosen for their interest, instruction, and variety. Two were the Battey-Tait operation, and in both there was no return of the menstrual flow, though the sexual function remained as before. The last and most interesting case of all was the removal of an œdematous fibroma of dimensions enormous, a very good photograph of the patient before operating being shown. Adhesions were found almost everywhere, the most difficult to manage being those attached to the liver and diaphragm. At the time of the detachment of the attachments to the diaphragm the patient ceased breathing, sank rapidly, and it was thought she must die on the table, but rallied under appropriate treatment. The case was manifestly one for drainage, but on account of the vast expanse of lax abdominal tissue he did not believe the serum would gravitate into Douglas's pouch sufficiently, and decided to defer drainage till necessary. Forty-eight hours after the operation the temperature reached 103.5° F., a few of the ventral sutures were removed and the abdomen flushed out with hot distilled water. Many blood-clots and much serum were removed, and the temperature fell to 101° F. within six hours. She died of septicæmia the fifth day after operation. He regrets that he did not resort again to flushing out the abdomen, as it seemed to improve her so much. Drainage in this case, though tried later, did but little good. Keith removed an œdematous myoma weighing 42 pounds. Tait, a uterine myoma weighing 68 pounds. This woman's weight was, before the operation, 199.5 pounds, after, 106 pounds, leaving a tumor removed weighing 93.5 pounds, which he believes to be the largest reported of the solid variety. The Doctor operates anti-

septically. Bleeding points are ligated with fine Japanese cable silk, the pedicle is always ligated and pocketed, the ventral wound is closed with silkworm gut, threaded upon two long veterinary needles, passed from within outward, always inclosing the peritoneum. He considers this the ideal suture, not only for the ventral wound, but also for the operations for lacerated cervix and peritoneum. For anæsthesia the Doctor uses exclusively the bichloride of methylene in a Junker's inhaler, and now, with an experience of its use in over three hundred operations of various kinds, he has not infrequently seen nausea, but vomiting only five or six times. When in doubt he always drains, and prefers Keith's glass tube over all others. He uses but little opium or morphia, on account of its locking up the secretions, but in case of pain uses antikamnia with happiest effects. He had much praise for the Staffordshire knot.

Joint Reflexes Consecutive to Pelvic Inflammation was the subject of a paper by Dr. W. W. Potter, of Buffalo. He discussed more particularly an exaggerated form of reflexes which were found about the larger joints, especially the joints of the lower extremities. On account of the close connection of the pelvic organs and the hip-joint through the cerebro-spinal system these reflexes are often found there. We frequently find severe intolerable aching in the lumbar region, low down backache, associated with pelvic disease. He related an interesting case of pain in the hip-joint occasioned by a fall, and which was treated for hip-joint disease for a long time, and was finally found to be due to pelvic peritonitis. The points to which the Doctor called special attention were the intimate anatomical relations between the pelvis and the large joints through the cerebro-spinal system, the importance of early diagnosis, and the important medico-legal questions which may grow up, and which did appear in the case reported.

The Clinical Teaching of Obstetrics in America was the subject of a paper by Dr. E. S. McKee, of Cincinnati, O. Entering into this subject in a spirit of criticism, the essayist found much to commend. The improvement had been marked since he last had occasion to investigate this special field. True, there is yet much room for advance, but we have cause for encouragement. Of all the civilized countries of the globe, our own, usually the leader, in this instance proved the laggard. There were some excuses for this, namely, that the time for study was too short, funds too meagre, the danger in a lying-in hospital too great, and the population too small and scattered to admit of obtaining material for the clinical teaching of obstetrics. These conditions exist at present in a much more limited degree. Every city in which the existence of a medical college should be condoned offers material which needs only to be grasped.

In many medical schools of our country, the science of obstetrics is admirably taught by pictures, models, and illustrations of various sorts, but the vast majority of medical students in America graduate without ever having witnessed a case of labor. Until within the last three or four years the majority probably equalled ninety-nine per cent. Many of our best teaching institutions have maternities connected with them. This is well, for here material is collected in small compass, and the student can see more in less time, being also under the supervision of competent instructors. Here he can be carefully inducted into the arts of inspection, mensuration, auscultation, percussion, and indagation. Then, too, the out-door obstetrical clinic has its advantages. There is a close similarity between this and the first experiences of the student in his practice. He will first be called to the hovels of poverty, where he must depend upon himself, and where he is developed. It would be well for this training to follow that in the maternity should both be at command. The ideal teaching of obstetrics is, first, a course of didactic lectures with quizzing; second, the observation and conduct of a number of cases in a maternity under the careful supervision of a teacher, quizzing following each case, the student making a written report; third, the out-door obstetrical work, where the student is left to his own resources, but instructed to call his teacher in case of complications, which instruction may be omitted with especially diligent students after considerable experience.

Would it not be wise for the Obstetrical Section of the American Medical Association, the light and guide of the American medical profession, urging it on to higher and grander views of medicine, to declare with one strong voice that the clinical teaching of obstetrics should be a part of the regular course in every recognized medical college in America. With the seal of such approval, those laboring in this field will be given great strength, courage, and hope.

(To be continued.)

Strychnine in the Treatment of Chronic Alcoholism.—Dr. V. N. Ergolski reports, in *Vratch* for March 7, 1891, ten cases of chronic alcoholism treated with more or less marked success by means of strychnine. The following are two of the cases reported in this article: The first was that of a gardener, thirty-four years of age, who often drank to excess, but did not regard himself as intemperate, claiming that he drank only when he had plenty of money and was in good company. At the solicitation of his mother, however, he submitted himself to treatment. On the first day he received a hypodermic injection of $\frac{1}{60}$ grain of nitrate of strychnine, $\frac{1}{40}$ grain on the next day, and $\frac{1}{20}$ on the third and following days. During the entire course of treatment, and for two weeks afterward, the patient did not drink anything, giving as his excuse that he had no money; but his mother said that he had never gone for so long a time without liquor in twelve years. Finally he thought he would try once more how vodka tasted. But after taking two glasses he became very drunk, had a violent headache, vomited profusely, and had to be taken home and put to bed. He tried the experiment again in a week or two, with the same result. He insisted, however, on resuming his old habits, saying that he did not want to lose his taste for drink, and began taking vodka, a few drops at a time, gradually increasing the dose until he could take his usual allowance without trouble. The second case was that of a railroad worker, who had been for ten years strongly addicted to brandy, so that every day he would take from a half to one bottle or more, feeling, unless he took this allowance, a great restlessness and a sense of drawing in the region of the stomach. He was anxious to overcome his habit, but had not the will-power to do so. The first day after coming under treatment he received a hypodermic injection of $\frac{1}{40}$ grain of nitrate of strychnine. Upon presenting himself the next day, he reported that he had had none of the restlessness or dragging at the stomach, although he had not touched a drop of vodka. Dr. Ergolski administered $\frac{1}{20}$ grain subcutaneously this and the seven following days, after which he dismissed the patient, giving him 1 grain of the remedy divided into sixty pills, of which he was instructed to take one a day every alternate week. On the fifth day of treatment the man attended the name-day festival of a relative, where he was pressed to join the others in drinking the health of the host. He felt, however, a loathing for liquor, and would not touch it although the company made sport of him for refusing. The patient reported to Dr. Ergolski at the end of fifteen months, at which time he was perfectly cured. The eight other cases were similar to these, in all of which there was some good effects noted—in some a permanent cure, though in a few there was a relapse from one cause or another. The author regards the remedy in the nature of a specific for chronic alcoholism, and declares, as his belief, that it is possible to cure even the most obstinate cases by means of it, although in cases of relapse it may be necessary to repeat the course of treatment once or twice.

Correspondence.

OUR LONDON LETTER.

(From our London Correspondent.)

FURTHER EXPERIENCES OF KOCH'S METHOD.

London, April 25, 1891.

Koch's treatment is again a subject of interest, and two important society meetings have just been held at which it formed the sole subject of discussion. The first of these "field days" took place last week, when a meeting of the Metropolitan Counties' Branch (South London District) of the British Medical Association took place at St. Thomas's Hospital. Dr. Bristowe opened the discussion and remarked that he had been from the first highly sceptical as to the value of the method, and an amused spectator of what was going on. He pointed out that infective diseases might be roughly divided into two categories, viz., (1) those which had a limited duration, and were in a greater or less degree self-protective, such as small-pox and scarlet fever; (2) those, like leprosy and tuberculosis, which were persistent and ingravescent, and in no sense self-protective. It was in relation to the former diseases that discoveries had hitherto been made by means of which the inoculation of an attenuated variety of the virus prevented recurrence. We knew nothing of the real nature of the protective influence thus imparted, but in such diseases it was not the mere presence of the specific organisms which caused mischief, but the poisonous matter which these organisms discharged. If such diseases as leprosy and tuberculosis were to be cured by injections, it could scarcely be by the injection of an attenuated virus, as they were persistent and ingravescent diseases not tending to cure. If curatively dealt with, it must be on other principles than those governing the other class of diseases. Dr. Bristowe said that when he first heard of Koch's remedy he believed, as many others did, that Koch had discovered something inimical to the bacilli; but when Koch told us that his remedy had no effect on the bacilli, but only tended to imprison them in an excess of inflammatory products, his scepticism became profound. When Koch's last instalment of confidence was given to the profession this mental attitude became more pronounced, for it was much less likely that aggravation of inflammation would checkmate the bacilli than that it would tend to encourage their growth and diffusion. Dr. Hawkins showed some cases of lupus which had been treated by Koch's method in St. Thomas's Hospital, and furnished a report as to a number of other cases treated there. Dr. Hector Mackenzie said that, now "tuberculin" was advertised as on sale at the chemists' it was high time the medical profession should learn what was thought of the remedy by those who had had opportunities of seeing its effects in hospitals. He contrasted Koch's statements at the International Medical Congress last August with those in his now famous communications of November, 1890, and January, 1891. Koch had said that hitherto physicians had failed to cure tuberculosis because they had gone about it in the wrong way, and tried the effects of various remedies on man, instead of on the parasites themselves in their pure cultures, and then on the lower animals. Koch talked of speedy cures of lupus and of early cases of glandular, bone, and joint tuberculosis, and regarded it as certain that phthisis in the beginning was curable by his remedy. Koch had led us to suppose that he had himself fully tested this wonderful remedy of his, that he had found that it prevented the growth of the bacilli in the test-tube, and we were surely not wrong in supposing that he had made numberless experiments with regard to its effects on tuberculosis in the lower animals. Two months elapsed, but the accounts of the fluid in Koch's further communication were bald in the extreme. Koch gave no indication of the length of time he had experimented with it, and the only experiments he told us of were a few on guinea-pigs. If he had made the experiments on animals which he had led us to assume he had done, surely he would have told us of them. Dr. Hector Mackenzie said the conclusion was forced upon us that Koch had suddenly left science for empiricism, and, after a few observations on tuberculous guinea-pigs, had proceeded at once to this gigantic experiment on tuberculous man.

Dr. Phineas Abraham said he could not go quite so far as Dr. Hector Mackenzie had done in denouncing Koch and his remedy. Dr. Abraham said he had himself had four months' experience of the method, having injected between forty and fifty patients. Most of the lupus patients had more or less improved—three in so marked a manner as to be regarded almost as practical cures. In a few there was no obvious improvement—one being a case of erythematous lupus of sebaceous type in which there was considerable constitutional disturbance, but only little local reaction. In none of the lupus cases had he pushed the remedy beyond twenty milligrammes, generally beginning with two milligrammes. A few cases showed skin rashes, the most severe being a scarlatiniform eruption in a boy followed by copious desquamation over the greater part of the body; this case turned out one of the best results. Dr. Abraham said he thought those cases acted best in which the lupus was hyperæmic and ulcerative; he was now combining with the method the application of salicylic and resorcin ointments. He thought there was much in what Mr. Hutchinson said as to the failure of the treatment to act on the myxomatous or "apple jelly" tissue of lupus; but he had seen in a few cases desquamation and diminution to some extent of such tissue. He had not seen the appalling effects from the injections recorded by the French surgeons, and he agreed with Dr. Leslie Phillips that the St. Louis report was just a little premature.

Mr. H. Betham Robinson showed a case of lupus treated by Koch's method. The patient had greatly improved, but it was feared the disease was returning. The success obtained in cases of tuberculous bones and joints had been limited, occurring to any certainty only in one case where there was an old discharging sinus; possibly the injections might be of benefit in such cases.

Dr. Wheaton said he had had the opportunity of watching a large number of cases treated by Koch's fluid, and had made post-mortem examinations in two cases subsequently fatal. In no case had he seen a permanent improvement, but in nearly all cases a temporary improvement occurred. The remedy certainly had no effect on the bacilli, and the changes described in them, such as beading and disintegration, occurred in cases not so treated. In several cases of phthisis he had found the bacilli more numerous after the treatment, and in tubercular glands he had been surprised to find a great increase in the number of bacilli in them under similar circumstances. He agreed with Dr. Bristowe that the fluid acted as a septic poison. It certainly caused the disintegration of caseous material, but he considered the treatment was not justifiable except in cases where there was a ready exit for the products of the breaking-down caseous material and no risk from the danger of a collection of pent-up pus.

At the Medical Society of London, on Monday evening last, Dr. Heron read a paper in which he gave a detailed account of cases treated by Koch's method. He divided his cases into three categories: (1) Those which, according to Koch, offered the best prospect of benefit. Of these, he was unable to affirm that any had been cured beyond danger of relapse. (2) Those in the second stage (consolidation). (3) Those with signs of cavities. In none of the cases previous to treatment was there any evidence of a tendency toward a cure, or even to be stationary. In a certain number of cases the patients had improved in health under the use of "tuberculin;" cough was less troublesome, night-sweats disappeared, and breathing was more free. There were also changes in the physical signs, the coarser râles gradually became

finer, getting less and less marked, to such an extent that it was sometimes difficult to distinguish between crepitation and a dry rub. This was the condition in the first class of cases, but it was applicable *mutatis mutandis* to the others. Dr. Heron said he thought the effects observed justified the use of the remedy in early cases of pulmonary tuberculosis. In lupus vulgaris the results he had seen had been so marked that he felt sure the remedy would soon be regarded as an essential part of ordinary treatment, but the danger of the reappearance of the disease was so great that, as Koch himself had said, auxiliary methods should always be resorted to.

Dr. Theodore Williams said he had tried the treatment in fourteen cases of undoubted phthisis, and considered its results to be disastrous. No matter how early the treatment was commenced, the injections were soon followed by the presence of lung-tissue in the sputum. Even as a means of diagnosis, he did not think the fluid was to be relied upon.

Dr. Radcliffe Crocker said that in some cases of lupus he had obtained more reaction from local injections than when the fluid was injected in the back. Latterly he had been in the habit of clearing out the diseased tissue by scraping, applying one or other of the strong acids, and then employing tuberculin. On the whole he thought that Koch's method must at the most be regarded as only a complementary treatment. It was too early as yet to say anything about the permanence of the results.

Dr. Waterhouse mentioned two cases in which he had tried the treatment. One of these improved considerably; the patient lost her cough and gained weight. He had also had satisfactory results in cases of tuberculous joint disease; in one case the patient made more progress in two months than he had previously made in two years.

Dr. Bagshaw said that in certain cases tuberculin seemed to bring about rapid destruction of lung-tissue, and mentioned a case in which, after thirteen injections, the middle lobe of the lung broke down and formed a large cavity; there were bowel symptoms, pains in the joints, and hæmaturia. Two months later these symptoms had disappeared, the cavity had practically healed up, and the patient was in a much better condition than at the commencement of the treatment.

Dr. Theodore Acland asked whether Dr. Heron considered it preferable to repeat the injections so as to set up a certain tolerance to the remedy, or whether it was desirable to space out the injections so as to allow of a reaction each time? He commented upon the fact that the remedy was still virtually a secret one.

Dr. Heron then replied and said he had seen nothing of the rapid formation of cavities. He thought Dr. Theodore Williams' experience must have been exceptional. With regard to local injections in lupus, he had himself found the injections in the back quite as effectual. After a time a sort of local tolerance was established, so that, if one changed the site of the injections, an increased effect would be observed. With reference to Dr. Acland's question, he had had the best results in those cases in which the early reactions were well marked, and in which subsequent reactions were less well marked. He looked upon this early reaction and subsequent diminution as a favorable sign.

The President (Dr. Douglas Powell) urged that Koch's fluid could not at present be regarded as a secret remedy. We knew its composition and the general method of its preparation.

A Training-School in Tokio.—In the training-school for nurses, attached to the Tokio (Japan) Charity Hospital, the course of study extends over two years, and includes anatomy, physiology, bandaging, theoretical and practical nursing, hygiene, and English. Twenty new candidates are admitted every year. There are now in the hospital over sixty graduates of the school. The hospital is supported by the ladies of Tokio, their annual subscriptions amounting to over twelve thousand yen.

Clinical Department.

STORMY CONVALESCENCE AFTER REMOVAL OF INTRA-ABDOMINAL TUMORS.[1]

By WILLIAM D. HAMILTON, M.D.,

COLUMBUS, O.

THE cases forming the subject of this paper are two in number. Hemorrhage and peritonitis, two sources of dread after such procedures, are here dealt with. They emphasize the point that, to have carefully done such an operation is not all that may be required to effect recovery. The surgeon's interest should not decline, even though, after operation, conditions be favorable. A watchful, experienced eye should supervise convalescence for a fortnight at least after removal of such growths. While the call for secondary interference may be urgent, action should be properly timed.

Special treatises have elaborated the technique of abdominal operations. In supra-vaginal amputation of the uterus for fibroid, most surgeons agree that, when practical, extra peritoneal fixation of the stump is the best method.

In Case I. it was dropped, and that which I feared took place: hemorrhage, and within a few hours; and it nearly killed the patient.

Having passed through this, she had peritonitis, with great distention and obstruction resulting from it. The latter condition supervened at a most unfortunate time. It occurred to a woman who had nearly lost her life from hemorrhage. She was certainly a poor subject for peritonitis. Operative revision was necessary at this stage to relieve her, and was successfully practised. Case II. shows that if there be doubt in the surgeon's mind in regard to the employment of a drainage-tube, he should use one.

CASE I.—Mrs. L. M——, of Bloomingburg, Fayette County, O., was sent by Dr. Foster, of Washington Court House. Twenty-eight years of age, married two years; no children and no miscarriages. Her menstruations were regular, but had of late years been very excessive. In 1885 her abdomen was seen to be enlarged. In June, 1887, after a tedious drive over a rough road, she had great abdominal pain, tenderness, and frequent scalding micturition. This lasted five weeks, confining her to bed. At the time of admission to Mount Carmel Hospital, in November, 1888, pain had about ceased. She was weak and anæmic from persistent menorrhagia. The abdomen was symmetrically enlarged to about the ordinary size of pregnancy at full term. The tumor was semi-fluctuant. Its relations to the womb could not be clearly ascertained. Operation, November 21, 1888, at 2.30 P.M., Dr. Charles S. Hamilton and Dr. Alan N. Dennison assisting. The incision brought into view a solid tumor that had started in the posterior wall of the uterus. The attempt to remove the uterine appendages elicited the fact that it would be impossible to do so without excising the tumor also. A temporary elastic ligature was cast about the stump, and enucleation of the mass was begun. Supra vaginal amputation was finally resorted to as the only practical expedient. The stump being large, the plan was adopted of hollowing it out and stitching it over and over from the bottom with continuous layers of gut. It was closely brought together, until ultimately the union of the peritoneal surfaces left it apparently secured. The provisional ligature was then removed. The appendages had been included with the tumor. The latter—a fibro-myoma—weighed eleven pounds. After cleansing the cavity with warm water, it was noticed that the stump had begun to bleed. The dissection had been carried so deeply that the outside method of fixation could not be done. It was then transfixed with a needle loaded with heavy silk and tied with a Tait knot. The utmost care was used in its application. This controlled

[1] Read at a meeting of the Northwestern Ohio Medical Association, December 12, 1890.

the bleeding effectually for the time. A glass drainage-tube was inserted into the cul-de-sac, and the wound was closed. Pulse 80, tolerably strong and regular. She was put to bed in good condition.

At 9.30 P.M. she was bleeding and her condition was very unpromising. Her face was pinched, pale, anxious, and cold. At 10.30 P.M. pulse, 135 and feeble. The dressings were saturated with blood, which was trickling over the abdominal walls. At midnight, pulse 156, barely perceptible and intermittent. Her breathing was rapid, her extremities were cold. She was restless and apparently moribund. The hemorrhage had ceased. During all this time the foot of the bed was kept considerably elevated. At 12.30 A.M. ten ounces of a warm saline solution were introduced into a vein in the forearm. It refreshed her greatly. She said that she could feel its warming influence. Her color improved and the pulse diminished in frequency and became stronger.

November 22d, 7 A.M.—Was free from pain, had taken some nourishment by the mouth and had retained it. The bleeding never recurred. There was some abdominal distention. A second saline transfusion of eight ounces was given at 8 P.M., and she grew temporarily better.

November 26th.—At 3 P.M. the pulse rapid, flickering, and could not be counted. The distention had greatly increased. Peritonitis with obstruction was present; for, in spite of the frequent and liberal use of salts and enemata in the previous three days, the bowels would not act. Death was again imminent. She was etherized and put on the operating table. The stimulant effect of the anæsthetic was very marked, for her pulse grew stronger under it. The lower five stitches were removed and a hand cautiously introduced. Dark, offensive fluid, and decomposing clots were found in abundance. Adjacent coils of intestines were generally adherent throughout the belly, and were liberated one from another with the fingers, the pedicle and its immediate environment being left intact. Warm boric solution was used to flush the cavity, a large quantity being required to cleanse it. The drain and stitches were reinserted. It was interesting to note the change in her facial expression, the improvement in pulse, and the marked subsidence of tympanites during the twenty-three minutes in which she was on the table. Her bowels acted freely half an hour later, and several times during the ensuing night. Next morning, at 7.15, pulse 132. The distention had receded completely and she continued to take food at regular intervals. Henceforth the only source of anxiety was the rapidity of the pulse, which was never less than 120, until December 16th, when a large slough came away with the Tait ligature. She was discharged December 25th, and has since remained well.

CASE II.—Miss J. G— , seen in consultation with Dr. Ranney, of New Albany, O., aged eighteen, had been growing large for two years. As a rule, has been regularly unwell since the fifteenth year, when menstruation began. The abdominal increase has been symmetrical and progressive. The courses were absent in February and March, 1889. There was very little abdominal pain at any time, although tenderness sometimes existed. Bowels regular. Facies ovariana well marked. Dulness generally present, excepting at the sides and above the growth, where the crowded intestines yielded resonance. Percussion sounds not modified by change of posture. Fluctuation in every diameter. Vaginal examination: uterus normal and movable. Diagnosis: simple ovarian cyst. Entered the hospital. Three days' careful preparation of patient.

Operation, August 2, 1890, 8.30 A.M., Dr. William K. Rogers assisting. Present, Dr. Ranney, Dr. Stephenson, U. S. Army, and others. Incision, four inches. Simple cyst, weighing thirty-five pounds, few adhesions, pedicle of small size. No difficulty at any stage of the operation. Cavity thoroughly irrigated with warm water. No bleeding of consequence. Wound closed with silkworm gut and no drainage-tube used.

August 4th, 8.30 A.M.—Patient perfectly comfortable, no pain; outlook good. 8.00 P.M.: pulse, 132, patient delirious and very restless, no abdominal symptoms; prescribed twenty grains of sulphate of quinine with as many drops of dilute sulphuric acid, dissolved in four ounces of warm water, and to be given by enema.

August 5th, 7 A.M.—A second dose of fifteen grains was given, as the first injection had not been retained. At 4 P.M., an abatement of symptoms; was taking nutrient enemata every four hours; took some nourishment by the mouth and retained it.

August 6th.—Pulse, 102; temperature, 102° F. Rested well during preceding night. No pain.

August 7th.—Pulse, 78. Bowels acted freely.

August 8th.—Pulse, 78; no tympanites; ate bread and tea this morning.

August 10th.—Pulse, 102; temperature, 101½° F. A tympanitic rounded swelling filling left groin and postpubic space. Cul-de-sac tender; some pain; enemata not retained.

August 12th.—Extensive peritonitis; general distention; belly and vaginal vault very tender. Pulse, 120. Countenance dusky, giving her a jaundiced look. Bowels acted slightly. Salts failed to produce a proper response. At 4 P.M. etherized, washed the parietes, removed four lower stitches, and found the wound united. Carried in two fingers. A quart of purulent fluid escaped at once; two or three diverticula, walled with intestines, parietes, or omentum were discovered. Intestines firmly united to abdominal walls at nearly all points about the field of incision. Cul-de-sac full of fluid. The main accumulations were below the wound, as indicated, and above it in the right loin. Washed freely with hot boric water. Inserted a glass drain and closed the wound. Bowels acted seven times during that night.

August 13th, 9 A.M.—Pulse, 72. All distention relieved.

August 26th.—Drain withdrawn.

September 3d.—Slight discharge of pus from lower angle. Discharged September 13th. Has since remained well.

The cases cited are unusual, so far as the necessity of secondary operative interference is concerned. Most of my cases in which operations for the removal of intra-abdominal tumors are required get along in an uneventful way. So far as the facility with which they get well is concerned, the presence of adhesions and of surmountable difficulties in an operative way do not seem to retard convalescence, provided they survive the shock.

It is comforting to know that in a percentage of cases of peritonitis, if ordinary remedial measures fail, we may have recourse to operative revision of the abdominal cavity with some hope of success. If all of the precautions as to cleanliness have been observed, and these are most exacting, a faultless technique should be followed by recovery in a large proportion of cases.

The manner in which peritonitis causes death is evident: The importance and large area of the membrane affected, it being the great open mouth of the absorbent system; the condition of obstruction, due to distention and adhesion of coils of intestine; shock resulting from diaphragmatic pressure; interference with respiratory and circulatory mechanism; the whole depending upon defective drainage or injurious manipulation of the peritoneum.

PURPURA HÆMORRHAGICA.

By AGNES LOWRY, M.D. PARIS,

ATTENDING PHYSICIAN TO CHILDREN'S HOSPITAL, AND CLINICIAN AT PACIFIC DISPENSARY, SAN FRANCISCO.

THE interesting and instructive paper recently presented to the readers of the MEDICAL RECORD by Dr. G. R. Lockwood is by far the most advanced that has yet been written upon this disease. It is very evident that the literature upon this subject, especially of the etiology and pathology, must be entirely rewritten to suit the require-

ments of modern teachings and the discoveries of modern science. Most of the articles heretofore written express the prevailing ignorance, in regard to origin and predisposing causes. The discovery of the bacteria, by Letzerich, pathognomonic of the disease, happily throws much light in this direction.

In response to the desire for discussion, expressed by Dr. Lockwood, I would like to present the report of a grave case of purpura hæmorrhagica which has recently been under my care.

J. S——, female, aged twenty one, medium height, pale, moderately well nourished, and of nervous temperament. Parents both dead. Cause of father's death unknown. The mother had phthisis, but the immediate cause of death was uterine hemorrhage. One uncle and one aunt have died of phthisis.

This patient was housekeeper, with four younger children to look after, and naturally some care and anxiety. She has suffered much from dysmenorrhœa since her arrival in the city, two years ago; is anæmic; is often attacked with faintness, and has had palpitation at times. She had been feeling badly for several weeks, when, December 4, 1890, after sweeping, she noticed small bluish spots over the entire body. These spots gradually increased in number until, when seen by me, December 8th, the entire body, with the exception of the soles of the feet, toes, and palms of the hands, was covered with purpuric patches, varying in size, from a pin's head on the extremities to those as large as half the palm of the hand on the back and sides. The neck, back, shoulders, and chest were sprinkled with them, the larger ones being ecchymotic in character. On the tongue three blisters the size of a lentil, filled with black blood, were found, and on the inner side of the left cheek two large bullæ, similarly filled, were seen. These, after a few days, burst and emptied. Fresh spots, red in color, appeared on the anterior surface of the neck and on the forehead, and a few small reddish points existed on the conjunctivæ. The pillow was stained by oozing of blood from mouth and nose, and the edges of the gums around the teeth were covered with brownish, bloody sordes. A slight epistaxis had appeared for several days, and the patient had been spitting blood, which apparently came from nose and throat. But the symptom calling for immediate attention was an intense uterine hemorrhage. The sheets and clothing were saturated, and a continuous flow existed, which had commenced the previous day. Had menstruated one week previously. Acute pains in the back and sides, and abdominal cramps and nausea, were complained of. Temperature and pulse normal. Prescribed ergot, 1 gr., opium suppositories for the pain, elevation of the pelvis, applications of ice, cold drinks, etc. The hemorrhage continuing, several hours later the dose of ergot was increased in quantity.

December 10th.—The hemorrhage being unchecked a hot vaginal douche was given, pulverized tannin and alum applied to cervix, and the vagina thoroughly tamponed. Ice, quiet, nourishment, and port wine *ad libitum* were ordered. For the intense abdominal pains 1-grain opium pills every three hours, or oftener if necessary, were prescribed, and for the metrorrhagia the following prescription, the ergot only seeming to add to the intensity of the abdominal pains:

℞. Gallic acid ..... ℥ ss.
Acid. sulph. dilut ..... ℥ j.
Tr. opii deod ..... ℥ j.
Infus. rosæ comp. ..... ad ℥ iv.
M. Sig.: One tablespoonful every three hours.

This had no effect upon the flow. The tampons were removed, and with them immense clots from the vagina. A hot alum douche was given, and after application of pulverized tannin the tampons were again inserted. Ordered:

℞. Hq. ext. ergotin (Bonjean) ..... 10 grs.
Aqua et glycerine ..... ℥ jss.
M. Sig.: One tablespoonful, to be repeated in four hours.

December 12th.—Patient weak and sighing, complaining of abdominal tenderness on pressure, and intense uterine and intestinal cramps. Temperature, 100° F.; pulse, 96. The uterine hemorrhage still continued; the tampons acting only as a sieve, retaining the coagulated blood and allowing the serum to pass through. There was a scarcely perceptible offensive odor. Removed tampons and clots from vagina; gave a hot bichloride douche, 1 to 4,000, applied Churchill's tincture to cervix, and tamponed vagina. From this was dated the gradual recovery of the patient.

December 13th.—Temperature, 100° F.; pulse, 120. Seemed better; eats with appetite; bowels regular; no pain.

December 14th.—Flowing recommenced after severe uterine cramps the previous evening. Severe headache and pain in back of neck. Hypodermic injection of ergotole, gtt. viij.

December 15th.—Slept none on account of headache and pain in back of neck. Had a sensation of intense itching over entire body. Flow diminished. Ordered phenacetine, grs. xxx., in two powders, for the pain. Ergotole, ℥ ss., by mouth if flowing recommenced. Removed tampons and gave bichloride douche 1 to 4,000.

December 16th.—Hemorrhage had ceased. Headache and pain in back of neck not relieved. Complains of pain and tenderness over entire spine. Examination of dorsal region showed a circumscribed red spot, the size of the palm of the hand, and very tender on pressure, over the sacrum. It was evidently the commencement of a bed-sore. The patient had been in bed but eight days when this was observed. Covered the place with adhesive plaster, and gave directions to lie on the side, and not on the back. Temperature, 100° F.

December 17th.—Slept well. Hemorrhage almost entirely ceased. No headache. Back less sensitive. From this time the patient made a somewhat slow convalescence, which was only interrupted by a rapid enlargement of the chain of cervical lymphatic glands on the right side, traceable to a small eczematous patch at the upper border of the right ear, which had existed several weeks previous to the attack of purpura, causing a slight induration of these glands. The heart, lungs, liver, and spleen, examined during the course of the malady, were found normal, and the pulse and temperature remained as in health.

Remarks.—As this disease is somewhat rare (excepting the forms of scurvy which are seen frequently in large seaports) until further experimentation is made all conclusions arrived at must be simply conjectural. But, as modern pathology tends to show, it is probable that *all* the forms of disease characterized by the symptoms constitutional infection and spontaneous hemorrhages may be included under one head. Even those classed by Dr. Lockwood as symptomatic, and excluded by him from those forms considered essential, will be probably found to be produced by the bacillus of purpura hæmorrhagica co-existing with some other, and occupying a secondary and inferior position in the production of the symptoms. The recent investigations of Cornil and Babès show the frequency of the co-existence in the blood of two or more species of micro-organisms in many infectious diseases. Thus is explained the production of the complications occurring in these maladies, as, for example, pneumonia in typhoid fever.[1] "Mixed infection," then, will explain the appearance of purpura in the exanthemata and in other infectious diseases, in endocarditis, in the purpuras of the newly born and in the lying-in, in rheumatism, and in the anæmic and cachectic.

Purpura rheumatica, or peliosis rheumatica, undoubtedly is one of the forms of purpura hæmorrhagica; but the term rheumatica should be abandoned as misleading. A case I treated about the same time as the preceding was to me most instructive. In the first stages it seemed a

[1] Medical Press, quoted by MEDICAL RECORD, February 21, 1891, p. 248.

simple urticaria. Later, I changed the diagnosis to erythema nodosum, but the final stages. when hemorrhagic spots replaced the nodes, showed it to be peliosis rheumatica, or purpura rheumatica, although no rheumatic tendency was present. Cause, apparently, sewer-gas poisoning.

It would be logical, it seems to me, to include in the same category with the purpuras, if not in the same class, those diseases (the various forms of erythema, erythema nodosum and purpura rheumatica) considered by Kaposi under the heading erythema exsudativum multiforme. They are described by the Vienna school of dermatologists as affections having identical anatomical changes, but varying in degree. As complications and results, especially of erythema nodosum, Kaposi mentions endocarditis, pericarditis, meningitis, tuberculosis, valvular disease, pleuro-pneumonia, and pneumonia, with a considerable number of deaths (10 in 70 cases collected by Lewin) as the results of such complications.[1] They are all accompanied by more or less reddening of the skin, which becomes bluish in color, and fades away like a bruise, showing more or less blood exudation. Polotebnoff[2] in an interesting article on the various forms of erythema, considers it an infectious disease, or rather a symptom of an infectious disease, which may or may not present a marked eruption.

The mortality in grave cases of purpura hæmorrhagica is high. In the cases reported by Dr. Lockwood there were 13 deaths in 17 cases, and in the total number of cases mentioned by him—30—there were 25 deaths.[3] Jaccoud[4] reports 61 deaths in 199 cases collected by Gintrac, and Dieulafoy[5] says, one-third of these grave cases are fatal. Consequently, it is extremely important to discover, know, and employ the proper therapeutic agents in combating the germ of infection. In the case I have reported improvement seemed to date from the first bichloride vaginal injection. In another case I should use the same remedy internally.

848 Van Ness Avenue.

DISLOCATION OF THE HEAD OF THE ULNA FORWARD, WITHOUT A FRACTURE OF THE RADIUS.

By CHARLES G. BRIGGS, M.D.,

GLOVERSVILLE, N. Y.

Mrs. H. R——, aged seventy-two. On January 18th the patient, in attempting to walk from near the head of her bed, toward the left, around its foot, became dizzy, just before turning the lower corner, falling forward upon her face. In attempting to save herself she grasped the foot-board with her left hand, placing it in such a position that the left half of the wrist was covered by the point of an overhanging scroll. As the arm went forward with the body the scroll-point applied itself firmly to the back of the ulna, holding it stationary, and thus dislocating the head forward.

Upon examining the case I found the ulnar prominence on the back of the wrist completely absent, and in its place a slight depression; anteriorly there was an unnatural fulness on the ulnar side of the wrist; the hand was supinated. Reduction was accomplished by extension from the hand, and counter-extension at the radius, the hand being forcibly pronated, and pressure used backward upon the head of the ulna. The patient, on account of shock from the fall, was obliged to keep her bed for several days, during which time hot fomentations were used and the arm allowed to lie naturally across the body.

Eight days after the injury, when the patient was carrying the arm in a sling, the joint became painful again, pronation and supination being accompanied with difficulty.

I found the bone partly slipped forward. I replaced it and applied a straight splint to the front of the arm, placing a compress under the head of the ulna to keep it in position. It immediately improved under this dressing, and in a few days the pain almost entirely subsided, though the splint and compress were used for several weeks to give the ligaments ample time to heal. All dressings have been removed now for three weeks, the joint being apparently sound. My apology for presenting this case is its rarity.

Hamilton gives twelve as the whole number of these cases recorded.

A CASE OF UNUSUALLY HIGH TEMPERATURE IN A CHILD—DISEASES OF CHILDREN AND THE PLAGUE OF OLD WOMEN.

By F. W. VAN DYKE, M.D.,

GRANT'S PASS, ORE.

A short time since I was called to see a child of fifteen months, sick with malarial fever. She had been ailing about five days before I was called. There was nothing unusual about the case, as the fever ranged from 99° F. to 102° F. until twelve hours before death, when it ran up to 105° F. I saw the little patient again four hours before death, and on taking the temperature I was surprised to see the thermometer register 110⅘° F. I immediately knocked down the register and proceeded to take it again, and it registered for the second time 110⅘° F. My thermometer is a Hicks certified, and I know it is accurate and in perfect condition. I think that this nearly, if not quite, beats the record. In fifteen years' practice I never saw any higher temperature than 107° F. until I met with this case. It may not be out of place to add that the child was always sickly, bottle-raised, and highly nervous.

On October 14th last I was called to see an infant of six months suffering from an attack of entero-colitis. There were from six to fourteen mucous and muco-feculent passages a day, tinged with blood. The baby had always been weak and was raised on the bottle. During the summer it had had two attacks of summer complaint from which it made a slow recovery, consequently when entero colitis set in it had not much vitality to resist the disease. The case dragged along for weeks with periods of gain, after which relapses would follow in the most exasperating manner. This condition of affairs lasted eleven weeks, when under the use of appropriate remedies and sterilized milk, combined with unremitting care and attention, the little patient recovered, much to my joy.

Meanwhile that ubiquitous cyclopædia of ignorance and misinformation had not been idle; I refer to the old women who are ever present on such occasions. They flocked in and recommended one thing and another as sure cures. One recommended a teaspoonful of paregoric every hour as being certain. Another wanted the mother to give it a teaspoonful of melted mutton tallow. Still another sent word that the baby's clothes had been changed too often; while others said the baby had its liver grown fast to its side and that it must be shaken loose. Consumption was also a favorite complaint with some. One woman sent word that she did not believe in doctors anyhow, and that if the parents would send the child to her she would cure it. Space is too short to enumerate the diseases and the remedies that were recommended; sufficient to say that the parents were intelligent people and had perfect confidence in me, and followed out my directions to the letter, for which I feel grateful. There were two points on which all these eminent therapeutists and clinicians agreed, and these were, that a change of doctors was absolutely necessary and "that the baby could not live three days longer." The parents have not yet been forgiven for not dismissing me,

and I am held up to odium because the child recovered. This may not be very interesting reading to some who doubtless would prefer something delightfully abstract and speculative, but of those who read this many will recognize it as a faithful picture of what occurs in every-day life. The great majority of women are born with an innate and profound knowledge of children's diseases, which remains latent until the fortieth year, after which it breaks out like a house on fire and reaches its greatest intensity at about sixty.

It is degrading and humiliating to think that physicians all over the country have to be exposed to the lying and slanderous tongues of such cattle as I have described above. Many a sensitive man has been goaded to despair by the meddling officiousness of such creatures, and I firmly believe that nine-tenths of the trouble among doctors in smaller places comes from the interfering of women who have more time to gossip than sense to use.

Instead of offering to help and be of assistance when people are in distress and suffering, these owls of midnight sit around and tell of all the terrible things that have fallen within their observation. They encourage women in labor by telling them of all the deadly complications that might happen, how Mrs. So-and-So died of fever afterward, and that if Dr. Blank had been in attendance instead of Dr. X. she would have recovered, and "that Dr. X. could not doctor a dog for her." They always predict death, and if the patient gets well they are grieved and injured. These are but a few of the trials that beset the doctor in country practice, and as long as they have always been with us, I suppose they always will be until the end of time, or until women cease to be born.

HOT WATER AS A REMEDIAL AGENT.

By LEVIN J. WOOLLEN, M.D.,

WASHINGTON, D. C.

Moist heat as a therapeutical agent has not received the attention from medical writers that its merits deserve. In the future the remedial effects of hot water are destined to play an important part in the relief of pain and the cure of disease.

It is not necessary to allude in this paper to the use of hot water as a surgical dressing after amputations, as that subject has been ably treated by Dr. Varick, of New Jersey. In the writer's opinion, hot water is excelled in such cases by dilute alcohol only.

In some cases of cholera morbus copious draughts of hot water, conjoined with injections of the same, will afford marked and speedy relief. For many years past the writer has used this treatment with such good effect that in some cases it was unnecessary to prescribe any drug whatever—even the usual hypodermic injection of morphine being dispensed with.

In a case occurring some years ago, the patient had been vomiting for three or four hours when the writer saw him. The cramps had become severe, causing him to utter agonizing cries. To relieve the severe straining produced by the vomiting, he was directed to take a large drink of water as hot as could be swallowed. This being ejected after a little while, a second draught was given which put an end to the emesis. As the attack had been caused by imprudence in eating, and as the bowels had not been moved, a large injection of very hot water was then thrown into the bowels. In a short time this was passed by stool, after which the injection was repeated. Relief from the cramps was speedy and permanent, and although I had charged my hypodermic syringe with one-fourth grain of morphine, I withheld the use of it for the time being, intending, as soon as the pain and cramps returned, to control them in the usual manner. The patient, however, soon sank into a sound sleep from which he awakened free of all trouble, except the debility and soreness that follow such attacks.

Since then I have pursued the same course of treatment in many cases, and although I have been compelled to use morphine hypodermically in some of them, yet the hot water has always proved a reliable adjunct in the treatment.

In cholera and cholera morbus, the cramps are supposed to be caused by the blood parting with its watery portion, thus sadly interfering with the general circulation. This being the case, it is plainly our duty to restore water to the blood as speedily as possible. Water is much more readily absorbed by blood-vessels when it is warm than when cold. By introducing hot water into the bowels as well as the stomach a large absorbing surface is reached by the fluid. In addition to this the effect of the heat on the terminal branches of nerves acts beneficially upon the circulation by stimulating the heart to increased action.

I have no doubt but that in Asiatic cholera hot water properly used will be found of more service than any other treatment. Given by the mouth and by injection through a rectal tube, it would, in my opinion, have a marked effect in bringing about reaction in severe cases; at least it is certainly worthy of a trial.

In cases of cholera that have passed into the stage of collapse, and when, under ordinary treatment, no hope can be entertained of the patient's recovery, I would not hesitate to make a small incision through the linea alba and flood the peritoneal cavity with hot water. The peritoneum absorbs water with great rapidity, and in cases of profound shock following operations upon the abdominal and pelvic organs, no other means acts as speedily and efficiently in restoring the circulation as does flooding the peritoneal cavity with hot water.

In the collapsed stage of cholera, where the pathology of the disease may be attributed to dehydration of the blood, it seems plain that to restore water to the blood as speedily as possible should be the main object of treatment. In such cases no organic lesions have occurred in any of the viscera of the body, but they are in a condition to resume their functions when their normal stimulus is applied to them. Hence if the fluidity of the blood be restored, and if the heart be artificially stimulated for a while by electricity, it would seem that death might be averted. These indications can most likely be met by taking hot water into the stomach, by injecting it in large quantities into the bowels, and in *extreme* cases, by flooding the peritoneal cavity with it.

1701 Ninth Street, N. W.

SWELLING OF THE FEET IN WARM WEATHER.

Dr. C. Ferdinand Durand, of Lockport, N. Y. writes: "The discussion of the possibility of idiopathic hydrops recalls a case I had brought to my notice the facts of which are as follows:

"Mrs. W——, blonde, aged thirty-two, mother of three children, perfectly healthy in every way, suffers during warm weather every summer from swollen feet and ankles; the swelling is often severe enough to prevent the wearing of her ordinary shoes. At other times, that is when the weather is not unusually warm, this swelling does not occur. Treatment was not asked for the condition, and I looked upon it as due simply to relaxation of tissues brought about by the high temperature and the dependent position of the parts.

"The trouble was worse at the menstrual periods, but no anæmic condition or organic lesion was present."

St. Paul's School, the military academy of Garden City, L. I., has been closed temporarily, owing to an outbreak of scarlatina. One cadet died of the disease. All the buildings have been fumigated, and every possible step taken to prevent the spread of the disease.

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from April 26, 1891, to May 2, 1891.

McKEE, JAMES C., Lieutenant-Colonel and Surgeon. Having been found incapacitated for active service by an army retiring board, by direction of the Secretary of War is relieved from further duty as attending surgeon and examiner of recruits at Philadelphia, Pa., and will proceed to his home, and report by letter to the Adjutant-General of the Army. S. O. 96, par. 3, A. G. O., Washington, D. C., April 28, 1891.

Official List of Changes in the Medical Corps of the United States Navy for the week ending May 2, 1891.

LUNG, GEORGE A., Assistant Surgeon. Granted two months' leave of absence.

HOEHLING, A. A., Medical Inspector. Detached from Navy Yard, League Island, and waiting orders.

JONES, W. H., Surgeon. Ordered to Navy Yard, League Island.

NORTON, O. D., Passed Assistant Surgeon. Detached from Naval Hospital, Chelsea, Mass., and waiting orders.

CORDEIRO, F. J. B., Passed Assistant Surgeon. Ordered to Naval Hospital, Chelsea, Mass.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending May 2, 1891.

	Cases.	Deaths.
Typhus fever	0	0
Typhoid fever	5	3
Scarlet fever	184	37
Cerebro-spinal meningitis	3	6
Measles	300	14
Diphtheria	67	12
Small-pox	2	0
Varicella	0	0
Pertussis	0	3
Erysipelas	0	0
Mumps	1	0
Rötheln	0	0

Diseases Prevailing in the Several Countries.—*Great Britain*—Scotland: Phthisis pulmonalis, croup, diphtheria, and rheumatism. England: Bronchitis, pulmonnitis, and all affections of the respiratory organs. Ireland: Typhus fever, including the exanthematic form, endemic, and permanent. Scrofula, largely prevalent. Recurrent typhus and enteric fever, generally diffused throughout the United Kingdom. Scarlatina in its gravest forms, very frequent; intermittent fever, very rare; small-pox and measles present no special features.

Holland.—All forms of intermittent fever, diarrhœa, dysentery, and hemorrhoidal diseases, general; phthisis pulmonalis, decreasing. Small-pox, of rare occurrence during a long period, epidemic in 1870–71. Alcoholism, mental diseases, and convulsions, rare by comparison with the percentage in other countries in the same latitude.

Belgium.—Phthisis pulmonalis, widely diffused, causing in the central portions of the country more than one-fifth of the mortality. In Brussels the number of consumptives is greater, relatively, than in any other city of northern or central Europe. Diseases of the digestive apparatus and the nervous centres, with rheumatism, predominate in the pathology of Belgium. Exanthematic typhus, recurrent fever, and cancer give a lower per centage than in contiguous countries. The same is true of alcoholism.

France.—Phthisis and inflammations of the respiratory organs; in southern and eastern France abdominal typhus is much diffused; malaria prevalent along the western and southern littoral; goitre and cretinism endemic in the mountain districts; cerebro-spinal meningitis frequently epidemic, as also miliary fever in the north of France. The last named disease is almost unknown in other European countries.

Spain and Portugal.—Malarial diseases, intermittent in the north, remittent in the south, associated with dysentery, and frequently fatal; enteric fever, frequently epidemic and malignant; yellow fever, imported by way of the sea in 1800, 1820, 1857, 1871, and 1878; mortality from phthisis unimportant along the coast, but frequent in the central provinces; cerebro-spinal meningitis, frequently epidemic; pellagra, scalius, and scleroderma, endemic in some provinces; syphilis, widely diffused and of very serious character.

Italy.—Malarial fever and pellagra are the most prevalent diseases. Pellagra, the genesis of which is coeval with the introduction into the country of Indian corn, infests the northern provinces; goitre and cretinism, endemic in Piedmont, Lombardy, Luguria, and Tuscany; typhus fever, apoplexy, and renal calculi, frequent. Cholera and plague belong to the eastern littoral. Yellow fever was imported into Leghorn early in the present century. At Malta malaria is unknown, while dysentery is frequent.

Switzerland.—Pulmonary affections, rheumatism, goitre, cretinism, and deaf-mutism are the diseases of most frequent occurrence.

Austro-Hungary—Malarial fever, bilious typhus, and recurrent typhus prevail in the Danubian provinces; dysentery, phthisis, cardiac affections, apoplexy, arthritis, and rheumatism, diffused; malignant syphilis, frequent; scrofula, enormously diffused.

Germany.—Typhus fever in the exanthematic and recurrent forms, frequent; epidemics of diphtheria, frequent and disastrous; neuropathy and apoplexy, very frequent; alcoholism, in the same percentage as in other countries; goitre and cretinism, endemic in the mountain districts; phthisis, less than in Vienna; dysentery and scrofula, rare. As regards trichinosis, Germany, and especially Saxony, is in the front rank of European countries.

Denmark and Iceland.—Pernicious intermittent fever, diminished; cancerous diseases, urinary calculi, alcoholism, and mental disorders, increased; phthisis, less frequent than in contiguous countries; small pox and measles occur in light form. In Iceland influenza and catarrhal bilious fever predominate; convulsions and tetanus of the new-born, frequent; also rheumatism, neuralgia, hysteria, and chlorosis; phthisis, unknown; malaria and syphilis, almost entirely absent. In a few districts scabies is endemic.

Sweden and Norway.—In Norway malaria is inconsiderable, while Sweden is seriously affected with it as high as 65° north latitude. In Norway phthisis has diminished; in Sweden it is widely diffused. Rheumatic affections and inflammation of the air-passages furnish an almost equal contingent of cases for the two countries. The same is true of diphtheria. Ophthalmic affections are confined to the northern provinces.

Russia.—Malaria is widely diffused in West and South Russia. Intermittent fever of a malignant type prevails along the banks of the great rivers that empty into the Black and Caspian Seas. Phthisis is rare in North Russia and in Siberia, but in Middle Russia, especially in Moscow and St. Petersburg, it attains a considerable percentage. Diphtheria has of late years appeared as a devastating epidemic. Violent epidemics of dysentery occur in the southern provinces at the close of the hot season.

Turkey in Europe.—Malarial and enteric fevers are widely diffused. Typhus fever in the exanthematic form is persistent in Constantinople. Diseases of the respiratory organs, due to variations in temperature, are very frequent. Syphilis is enormously diffused. The plague has not appeared since 1842.

Greece.—Intermittent and remittent fevers, with gastric and cerebral complications, predominate. During the winter acute and chronic rheumatism and chronic pleuritis prevail. Phthisis is quite frequent. Syphilis, cholera, scabies, and plague have never prevailed in Greece to the same degree as in contiguous European and non-European countries.

A Primitive Cæsarean Operation.—Dr. J. B. Baskerville records the following unique case: There was a Cæsarean section performed by a quack, along in the fifties, in the County of Bland, Va., under peculiar circumstances. The quack never attended medical lectures anywhere. The only knowledge he had of anatomy was gained from his book. The section was performed upon a woman who had given birth to children before the operation, without assistance, and in like manner afterward. The details of the operation were not divulged by the operator; nor did he give the indications, as he understood them, for operative procedure.

Voluntary Constipation.—In an article in the *Revue de l'Hypnotisme*, entitled "Voluntary Personal Uncleanliness," Dr. Galippe calls the attention of the authorities to the necessity of reforming the sanitary arrangements obtaining in most French educational establishments. Some facts related by him in this connection will be read with astonishment by those who are not familiar with the horrible filthiness of most French closets. He says, "We need hardly remind the reader of the disgusting filthiness of most (school) closets, and I have known sensitive children who refuse to repair to these places until they were absolutely obliged to do so, such is their horror of the stench that there assails their nostrils, and the dirt they may bring away with them. I have known of many children who have suffered much from this voluntary constipation, and of others who, affected with diarrhœa, have for a whole week passed their motions into their clothing." Dr. Bourneville, in a notice of this article (*Progrès Médical*, February 14th) says that he has for years urged the necessity of endowing not only schools but also hospitals and barracks with decent closets. He has endeavored to convince the French public of the feasibility of such a stupendous feat by having constructed for his idiot and imbecile child-patients at the Bicêtre closets, the cleanliness of which strikes the French visitor with astonishment. M. Bourneville also demands for each school a complete set of bath-rooms, and calls for regulations rendering the use of a bath obligatory on the scholars.—Paris Correspondence of *The Lancet*.

Better than Koch and Brown-Séquard Combined.—Dr. Caius, some four hundred years ago, when an old man, tried to regain his youth by sucking the breast of a woman. He died of stone—not of old age, at least. A more successful application of this remedy is reported to us by a correspondent, who says that "a party who had every indication of the last stages of consumption has regained former health, and attributes it to obtaining his nourishment from sucking a healthy nursing woman."—*Dixie Doctor*.

Hunger and Infection.—It is a well-known fact that hunger predisposes to certain diseases, but it has been reserved to two Turin doctors to demonstrate the increased liability experimentally. Their observations were carried out with the virus of bacillus anthrax on pigeons, a disease to which these birds are, under ordinary circumstances, refractory. They found, however, that six days' total deprivation of food rendered the birds amenable to the virus, on condition that food was still withheld. If, however, food was given at the same time as the virus, then they still successfully resisted infection. Further, when starvation was continued for two days after the inoculation, and food then given, the development of the disease, though not prevented, ran a slower course. Lastly, the virus proved capable of infecting birds well fed up to the date of inoculation, but starved subsequently. The line of investigation is evidently one which admits of further research, but the moral is obvious.—*Medical Press and Circular*.

Gum Arabic, which was once universally used, has become very scarce and dear, and a substitute for it is being made from starch.

Treatment of Pigmentation in Pregnant Women.—In the *Journal de Médecine de Paris*, the following ointment is recommended to be rubbed into the affected parts twice daily, to remove the pigmentations which so often disfigure pregnant women:

℞. Cocoa butter,
Castor-oil.....āā ʒ ij ʒ.
Oxide of zinc..... gr. v.
Yellow oxide of mercury..... gr. ij.
Essence of rose, enough to perfume.
—*Therapeutic Gazette*.

The Cure of Persistent Dandruff.—The following is recommended in the *Lancet* by Mr. Purnell for the relief of this troublesome affection: An ounce and a half of iron wine, one drachm of liquor arsenicalis, three drachms of syrup, water to two ounces. Of this one drachm is to be taken in water after meals. Then an ointment consisting of four drachms of the red oxide of mercury ointment, an ounce and a half of benzoated lard, and two minims of the essence of bergamot should be rubbed thoroughly into the roots of the hair, and its use continued for some time.

Sneezing One's Teeth Out.—The report of the physician in charge of the Ningpo Missionary Hospital for the past year contains some interesting observations on tooth-drawing in China. Dr. Daly remarks that Chinese teeth are much more easily extracted than those of Europeans. The native dentists are said to possess a wonderful powder, which is rubbed on the gum over the affected tooth; after an interval of about five minutes the patient is told to sneeze, whereupon the tooth falls out. Dr. Daly has offered a reward of $100 to anyone performing the operation in this way in his presence, on condition that he is allowed to choose the tooth and examine the mouth before and afterward. So far no one will consent to perform the operation on these conditions.—*British and Colonial Druggist*.

Treatment of Carbuncle.—Dr. J. L. Napier, of Blenheim, S. C., uses pure carbolic acid locally in the treatment of carbuncles. He paints the whole carbuncular mass with pure carbolic acid three times a day, until the mass begins to lessen and the slough is detached. If the carbuncle is seen before suppuration has begun, in three or four days it will abort. The treatment, as above described, reduces the time of treatment from weeks to days; and besides that, the acid, being a local anæsthetic, adds very much to the comfort of the patient by relieving the pain—so much so that, after the first application, very little anodyne is needed.—*North Carolina Medical Journal*.

Regulating the Price of Drugs.—The Medical Department of the Ministry of the Interior in Russia has recently issued a price-list of medicines, by which the prices of seventy or more staple drugs have been reduced to a very low rate. The measure was adopted in consequence of the exorbitant charges made by many of the apothecaries in the large cities. The publication of the price-list is accompanied with an order stating that any druggist who charges a higher price for his medicines than the official list prescribes will incur the penalty, upon conviction, of a heavy fine.

OBSERVATIONS ON RATIONAL THERAPEUTICS.[1]

BY S. HENRY DESSAU, M.D.,

ATTENDING PHYSICIAN TO THE MONTEFIORE HOME, PHYSICIAN FOR DISEASES OF CHILDREN, OUT-DOOR DEPARTMENT MOUNT SINAI HOSPITAL, NEW YORK.

AT the present time there can be no possible doubt in the mind of any seeker of truth in the domain of medicine that rational therapeutics *must* be founded upon the correct relationship existing between the physiological action of drugs and the manner in which the causation of disease affects the healthy state. This proposition implies a full knowledge of physiology, and in order for this knowledge to be of use in the application of remedies to correct diseased action we must also have an equal knowledge of the manner of action of the causation of disease upon the physiological process. Here has been the wider field of investigation in later years, and such immense progress has been made in this direction that many ideas held concerning therapeutics as taught by former leaders of medical thought have now been almost, if not entirely, abandoned. Nevertheless, there have been faithful and diligent workers quietly investigating the study of physiology in the laboratory, who, with improved methods and instruments of precision, have, after most careful and fully confirmed researches, gathered together a store of facts that is serving as a foundation upon which to build a more correct system of therapeutics.

The necessity and timely need for a better therapeutical guidance is clearly indicated by the frequent contributions to medical literature on this subject, both at home and abroad, by writers who recognize the uncertainty of our present method. For when we look about us and take a mental survey of the medical situation we find but little progress has been made toward a more certain means of cure. There are various forces at work to explain this condition. Since the rapid advancement that has been made in medical knowledge in recent times, the principal direction of thought has been to discover, as I have before hinted, the causation of disease, and, if possible, a means to remove it, which would make the way to a return to the healthy condition plain sailing. "With the removal of the cause the effects would cease." In this direction the discovery of microbes as the specific agents of contagious disease has led up to an immense field of investigation which will undoubtedly largely assist in causing a reformation of our therapeutical ideas. But I do not think it venturing too much to say that further researches in bacteriological pathology will, with perhaps few exceptions, show that our main dependence for the successful treatment of diseases, so caused, will be required to be based upon the physiological action of remedies, and a correct application of such action to the diseased condition.

The question has been already raised whether the symptoms of disease caused by the introduction of microorganisms into the blood were the effect of the germ-poison itself, or a product emanating from the growth of the germ upon the blood and tissues. This product, resembling an alkaloid in its chemical behavior, and known as ptomaine, will, there is every reason to believe, hereafter enter largely as an important factor in the discussion of the etiology of disease. The action of ptomaines upon particular organs and nerve-centres has already been studied by Brieger and Brunton, with special reference to their production and destruction during the process of normal digestion. It is stated by these authorities that when the blood is charged with ptomaines in quantities larger than can be removed or destroyed by the liver, symptoms of poisoning are produced, in consequence of an irritation of the nerve-centres from the blood that flows through them. Under the influence of drugs acting as stimuli upon the hepatic function, such symptoms can be prevented by urging the liver to increased action and consequently complete elimination of the ptomaine.

Thus we see that it is not at all improbable that germ-diseases may depend for their successful treatment upon remedies administered upon the principle of their physiological as well as their antiseptic action.

On a closer examination of facts with which we are acquainted, derived from the natural history and management of disease, we find that the wisest and often most successful plan of treatment is to aid nature in her own method of restoring the healthy equilibrium. In this I believe that the physician is simply fulfilling his true calling, by acting, as he has been called, as the intelligent handmaid of Nature.

This view need not conflict with the simpler one, of a removal of the offending cause, which appeals with a mighty force to our reason. For though there are many causes of a gross character, such, for example, as a stone in the bladder or the intestines filled with undigested matter that may be easily removed, there are many other causes of disease of a far more subtle nature (such as any of the micro-organisms, or abnormal chemical products, the result of a bad manner of living or hereditary influence, which, mingling with the blood, produce all manner of disturbance in the economy through irritation of the nervous centres, and through these, the vascular mechanism they control) that can only be removed, if at all, by an exaggerated action of some contrary or compensatory arrangement.

Right here it may be remarked that the grand stimulus to the progress of surgery in recent years is due to the reliance upon the fact that this noble art was capable of demonstrating, both to the laity and the profession, that where the cause of a disturbance of health was of such a character that it could be reached and removed, no matter in what part of the body it was located, a restoration to health would be secured and life prolonged.

Another prolific cause of disturbance of the healthy state is inherent to the nerve-centres themselves. As such are those conditions, the result of over-taxation of the cerebro-spinal functions, where the presence of a chronic congestion eventually produces organic changes in the nerve-cells. This chronic congestion is evidently the result of an increased blood-supply to the parts, depending upon some reflex irritation of a vaso-motor fibre, originating in an emotion or similar disturbance of a higher centre. In this large class of affections the cause, though often plainly inferred, is of an evanescent character, but leaves behind a more or less lasting impression. As such, for example, might be mentioned those obscure disturbances of nervous function said to be caused by a fright, a sunstroke, or severe mental shock; also those long trains of symptoms of reflex origin, the effect of previous excesses.

[1] Read before the Northwestern Medical and Surgical Society.

It is evident that in such instances of diseased action our attempts at therapeutics cannot be directed against the removal of the cause which has fled, but more properly to a restoration of the normal function. An ancient aphorism in medicine is, that "where the increased flow of blood is, there also is the seat of irritation," the reverse of which is equally true. Next to the removal of the cause, the most important object to be attained in our therapeutics is the controlling of the increased blood-supply to the affected part. To accomplish this purpose we must depend mainly upon the physiological action of drugs, and to clearly understand and appreciate such action, a proper knowledge of physiology is indispensable. Brunton emphasizes this by citing the interaction of function that often occurs as the effect of a drug action, that can only be understood by a clear knowledge of physiology. Thus, curare when applied to a wound causes death by paralysis, but when given by the stomach death occurs from convulsions. The same ultimate effect occurs in both instances, only in the latter case paralysis of the respiratory centres occurs before there is complete paralysis of the motor nerves of the extremities, and the convulsive movements are the expression of irritation of the nerve-centres from being supplied by venous blood, the direct result of imperfect respiration from paralysis.

The investigation of the physiological action of drugs, begun by Magendie, Storck and others, a little more than a century ago, has received considerable impulse from more recent researches in physiology, both of which have advanced hand-in-hand and have furnished us with some most important facts. Perhaps the most conspicuous among these to be noted are the influences of the drug action upon the vaso-motor nerves in controlling the blood-supply to particular areas, which will be referred to later on; the preference of the effect of the drug action upon certain organs and tissues, or the so-called elective affinity; and the fact that in all manifestations of the drug action when fully developed, a double action is produced. It is to this double action of drugs that I wish to direct especial attention. I think it can best be studied in that class of drugs that affect principally the nervous system, and have hence been termed neurotics.

Of course it is well known that the bulk of our knowledge concerning physiology, as well as the physiological action of drugs, has been derived from laboratory experiments upon animals. This knowledge has been applied to the human economy, always with certain saving clauses for the difference of structure and degree of creation that will render a precise comparison impossible. Nevertheless, many of the facts obtained have been confirmed therapeutically upon the human body. The one scientific remedy that has been given to medicine was discovered in this way. It is needless to mention nitrite of amyl, introduced by Lauder Brunton in the treatment of angina pectoris.

It is evident from the works of ancient medical writers that the double action of drugs was known from the earliest times, but in an indistinct sort of way only, and that based upon observations of their action in the diseased state. It was a phenomenon that called forth vague and fanciful speculations from certain active minds, as its demonstration grew more familiar, and it is only quite recently that it has been studied in a rational manner. Ringer, Brunton, Phillips, Rubagliati, Ross, and Sharp in England, Schultz and Peiper, in Germany, and Bartholow, Smith, Reed, May, Mayer, and numerous others in this country are some of the workers in this direction. The testimony from all sources goes to show that, in all carefully conducted and recorded experiments, the primary effect of a drug, as manifested in physiological disturbances, is the direct contrary of the secondary or more fully developed effect of the drug

This can be all the more clearly demonstrated according to the class of drug employed and the quantity in action, for where the dose is large and the form favorable for rapid absorption, the primary effect will be of such short duration as often not to attract attention.

For purposes of illustration perhaps I could not do better than refer to a most interesting and instructive paper on this subject by Dr. Boardman Reed, published in the April and May numbers of the *London Practitioner* for this year (1888).

In this paper the author refers to the fact that many drugs, in small or moderate doses, acting as stimulants, exert a depressing effect when larger doses are given, or the small dose continued for a great length of time. This statement is by no means new, and has been explained by pharmacologists on the ground of an over-functional activity, leading to a condition of paralysis or exhaustion. But the fact that those drugs known as sedatives should have a primary physiological stimulant action, as demonstrated by Schultz and Peiper of the University of Griefswald, especially in reference to conium and curare, and corroborated by Nothnagel and Rossbach, is not so familiar to the medical profession, and if so, is not properly regarded in practice.

I have said that the double action of remedies is best studied for the most part in that class of drugs known as neurotics, to which class may be referred most properly, I think, both stimulants and sedatives. There is one other class of remedies that appears to affect particular organs, that also illustrates the double action of drugs in a remarkable manner. Professor Rutherford, of Edinburgh, has given us the clearest and most beautiful demonstration of such action in his report of the action of cholagogues upon the liver of the dog.[1] But here we find quite a different explanation given for the apparent double action of the drug employed. With podophyllin, for example, Rutherford found that large doses diminished the secretion of bile, but increased the purgative function of the intestines; moderate doses first increased and then diminished the bile secretion, while smaller doses prolonged the increased secretion of bile. It is reasonable to infer that the smaller doses of podophyllin increased the bile secretion by virtue of a stimulation of the inhibitory vaso-motor nerves controlling the hepatic circulation, thus causing dilatation of the arterioles and an increased flow of blood to the part, while the large dose caused an over-irritation or paralysis of the same fibres, or perhaps a stimulation of another class, namely the constrictor nerves, causing a contraction of the small blood-vessels with the result of a diminished blood-supply to the organ and a deflection of the circulation from the liver to the intestines, hence depressing the function of the liver and increasing the intestinal action. We have a similar illustration in the action of corrosive sublimate as a cholagogue, and here the therapeutical effect is well shown when this salt of mercury is given in small doses from the $\frac{1}{100}$ to $\frac{1}{50}$ of a grain in severe disturbances of the large intestines, as dysentery. The stimulation of the bile secretion by the small doses employed, produces a derivation of the blood supply from the inflamed area to the liver, thus relieving the engorgement and so acting as a revulsive. There are many more illustrations of a like nature that could be cited, but these two are sufficient to convey my idea.

In our estimation of the physiological influences just described, which have a broad application in therapeutics, it would be well to bear in mind, as pointed out by Foster, that the nervous influences, leading to either arterial dilatation or constriction, differ in degree only, not in kind, and may be considered as merely phases of the same action. These influences will perhaps be more clearly understood if I may be allowed to quote the following explanation of the working of the vascular mechanism as given by Foster in his text-book of physiology. Local dilatation of arterioles encourages a copious flow of blood through the area where the dilatation is taking place, and by reducing the blood-pressure, hinders the flow of blood into other areas. Local constriction, on the other

[1] London Practitioner, vol. xxiii., p. 235.

hand, lessens the flow of blood in the particular area, and by heightening the blood pressure tends to throw the most of the blood into other areas. By augmenting or inhibitory influences (constrictor or dilating) applied either to peripheral mechanisms or to cerebro-spinal centres, and called forth by stimuli either intrinsic and acting through the blood, or extrinsic and acting through nervous tracts, the supply of blood to this or that organ or tissue may be increased or reduced; the surplus or deficit being carried away to or brought from either the rest of the body generally or some other special organ or tissue. Physiology further teaches us that what was just before referred to as differences in degree of nervous influences means, that while a slight irritation, or stimulus so-called, of a nerve cell or fibre will cause an augmentation or exaggeration of its normal function, an excessive or frequently repeated application of such stimulus will cause exhaustion of the nerve force, which will be indicated by either a paralysis or cessation of its function, or the increase of a compensatory action, known as inhibitory, owing to the disturbance of the normal equilibrium of the mechanism. I think that there is much reason to believe that this is the rational explanation of that phenomenon of drug action known as reaction.

I have long thought that a more rational therapeutics could be founded upon the utilization of the primary physiological action of drugs when given in their minimum quantity to produce this effect, eliminating from consideration, of course, all chemical antidotal actions that drugs possess. I believe that I was one of the first in this country to call attention to this point, in a paper that I published in the New York MEDICAL RECORD, July 28, 1877, upon "The Value of Small and Frequently Repeated Doses." Since that time the subject has been taken up by many worthy members of the profession in all sections of the country, and the medical journals have contained frequent references to it. To my mind it presents many advantages, chief of which is the simple and rational principle of applying the uncomplicated action of a drug to a diseased action, which is of a like uncomplicated nature, as a means of cure. That is to say, we obtain the action of the remedy without its consequent reaction, which in this instance would be equivalent to the restoration of normal physiological action.

The secondary advantage of giving a remedy with little or no disagreeable taste, either in the form of a small sugar-of-milk tablet or an aqueous solution, is not to be slightingly regarded, not only in our practice among children but also with adults of a delicate and fastidious taste.

I have endeavored to show, without going too deeply into details, that a certain class of drugs affecting the nerves and another the special organs and tissues, have an undoubted double action, the primary or initial action being the direct contrary of the secondary or complete physiological action; and that the primary action, being, so to say, devoid of reaction when obtained from an exhibition of the minimum dose, can be scientifically applied for its direct action against those disturbances of the economy corresponding in their effects to the secondary or full physiological action of the drug employed.

The question of dosage necessarily becomes one of the highest importance, and it behooves us to turn our attention with all due judgment and deliberation to a reformation of this subject.

47 WEST FIFTY-SIXTH STREET.

The Decimal System in Russia.—The Russian Government has recently issued a decree to the effect that the decimal system of weights and measures shall be the only legal standard in the empire after the expiration of five years from this date. This will leave the English-speaking nations alone in their refusal to adopt the new system. The use of the decimal system is legal in this country, though not obligatory.

SOME UNUSUAL CASES FROM DERMATOLOGICAL PRACTICE.

BY GEORGE T. ELLIOT, M.D.,

DERMATOLOGIST TO THE DEMILT DISPENSARY AND THE NEW YORK INFANT ASYLUM; ASSISTANT PHYSICIAN TO THE NEW YORK SKIN AND CANCER HOSPITAL, ETC.

CASE I. *Acute Circumscribed Œdema.*—The patient, male, aged forty-nine, came to my office in September, 1890, for a trouble which had lasted for eight months. He had always enjoyed good health up to a month before the inception of the disease, being also a strong, stout, and functionally healthy man. At that time he had had attacks of constipation alternating with diarrhœa, and, during the existence of this condition of disturbed function the process developed. It began on the feet, in the form of an elastic swelling as large as a hen's egg, which itched somewhat, and which disappeared at the end of twenty-four hours. Since then he has had many attacks, sometimes an entire foot, or both hands or knees becoming suddenly enlarged to a great size, and after persisting for twenty-four to thirty-six hours, becoming normal again in appearance. On other portions of the body lumps, the size of eggs, or larger, would also arise, or the face might become swollen to twice its natural size, or the lips would protrude like two "sausages," or the nose would be as large as an ordinary lemon. The tongue has, likewise, been affected so that he could not speak or swallow, and twice he was nearly suffocated by the swelling in the throat. With each attack of the œdematous swellings there have also been outbreaks of ordinary urticarial lesions on various portions of the body, and these would persist for a few days after the disappearance of the former manifestations. The patient states that the appearance of the swellings was always preceded by an uncomfortable sensation, an itching and formication in the portion of the skin to be the site of the lesion. After their development, they would remain stationary or gradually disappear, rarely remaining present longer than thirty-six hours. The itching from the urticaria has been so severe and the distress occasioned him by his disease has influenced him so greatly that he has suffered from loss of sleep and appetite, and has lost thirty-eight pounds in weight. In June, 1890, he was advised to take belladonna. Since doing so he has gotten much worse, the recurrences of the trouble have been more frequent, and the pruritus more intense. He has also noticed that similar conditions arose whenever he allowed himself to get costive.

When he came to me the entire right cheek was swollen to double the size of the left one. The skin was not reddened, but of the same color as the unaffected side, and the swelling was elastic and somewhat tense. The itching was only slight. Over the body were numerous lesions of ordinary urticaria, scratch-marks, and pigmented spots. The bowels were very costive, moving only every three days, and only then after large doses of pulv. glycerrhiz. co. The treatment recommended the patient consisted of laxatives, his diet was regulated, and he was advised to leave off alcohol in every form. He did very well for a few weeks, but was seen in the beginning of November, suffering from a severe attack situated in the pharynx, the tongue being also affected, and his right cheek as well. He had allowed himself to get costive again, and, besides, had been drinking whiskey—five or six times daily—for several days previous to the attack. Simultaneously with the swellings there had also appeared numerous lesions of urticaria over the trunk and extremities. These were of all sizes, but mostly that of a twenty-five cent piece.

The diagnosis of acute circumscribed œdema should offer no difficulty, if the development of the localized swellings and their course are observed. In connection with the disease, general disturbances of various kinds have been observed, these being gastric, intestinal or renal, or of other nature; in one case malaria was the

inducing cause, and it was cured by quinia. In an example of the disease reported by me in the *Journal of Cutaneous and Genito-Urinary Diseases* (January, 1888), constipation seemed to be at the base of the trouble, in that feature agreeing with the case whose history is given here. In this latter the presence of the urticaria and its appearance coincidently with the development of the swellings was a most interesting fact. It would seem to emphasize the close relationship existing between urticaria and circumscribed œdema, that is, that both are only forms of an angioneurosis, originating in a reflex manner from a cause operating in some distant portion of the body, which cause might be gastric, intestinal, or of other nature. Except that the clinical manifestations of the latter are deeper-seated and subcutaneous, and that itching is absent, both have very much the same manner of behavior and course, as far as their objective lesions are concerned. In this case, as well as in two others which have been treated by me, outbreaks of the œdematous swellings occurred whenever there was any gastric or intestinal derangement, but they remained away, for the most part, as long as constipation or any other functional disturbance of the intestinal tract was absent or guarded against; still, relapses were of frequent occurrence. The lesions remained present usually for twenty-four to thirty-six hours after their development and then disappeared without leaving a trace. This is substantially the same course as is followed by an urticaria, though it must be granted that there are qualitative differences between the two eruptions, but yet these are only such as may be said to depend upon the difference in their situation in the skin. Contrary to what is the case in urticaria, however, the prognosis in these cases is not so favorable a one, as relapses continually occur, the disease running a chronic course, and at times producing most alarming symptoms of, for instance, suffocation, when the pharynx or glottis is attacked by the process.

As far as the treatment is concerned, it can only be said that whatever appears to act causatively in producing the eruption must receive proper attention, and, in addition, every possible source of reflex irritation must be removed. There are no special remedies indicated, none which seem to act directly upon the angioneurotic disturbance in the skin, but those from which benefit may be expected are the same as are required for the removal of any systemic derangement which may exist uncomplicated by attacks of circumscribed œdema.

Case II. *Multiple Syphilitic Initial Lesions.*—Benjamin A— , aged twenty-three, married, consulted me at the Demilt Dispensary, on February 8th, 1890, for a sore on the penis. He had had connection with a prostitute on February 1st, and five days later had noticed the lesion situated on the prepuce, just behind the corona. It was a typical chancroid, and a couple of days after I saw him a new one appeared near the first one, probably from autoinoculation, as he was careless as to cleanliness. These lesions healed under iodoform, and were not accompanied nor followed by any glandular enlargement.

The patient was seen again on April 15th, presenting on that date a patch of herpes simplex about midway on the right side of the penis. It healed up under bismuth subnit. in three days. He was seen again on May 6th, and gave the following history: On April 22d he had noticed a hard papule on the site of the former herpetic patch. The lesion had become excoriated in a few days, and subsequently ulcerated. On the 26th he observed another and similar papule on the dorsum, near the root of the penis, and on the next day still another, on the left side of the penis, nearly opposite the first one. On the 30th a papule appeared on the prepuce, near the frænum. These dates are probably only approximately correct, being the statement of the patient alone, and consequently they cannot be taken too strictly. When I examined him the first and second chancres had become deep, excavated ulcers, with precipitous edges, elevated borders, and bases of cartilaginous hardness, and upon them were thin, greenish crusts. The third lesion was a papular elevation seated on a hardened, sclerosed base, and it was covered by a thin, fissured, yellowish crust, beneath which was an eroded, but not ulcerated, base. The sore near the frænum was flat and dense, but not eroded. The inguinal glands on both sides had begun to enlarge indolently, were quite perceptible to the touch, and slightly painful.

During the following week the lesions increased in size, the first one becoming as large as a two-cent piece, the others varying from a dime to a three-cent piece, and showed no tendency to heal. Under an aristol. (twelve per cent.) ungt., applied in the second week, they did gradually improve, ceased enlarging, and progressed toward cicatrization, though this was not completed until some weeks later and after he had been placed on specific treatment. During the time that intervened between the first visit and May 22d, polyadenitis ensued, the cervical, cubital, anterior and posterior auricular, and other glands becoming indolently enlarged. On the latter date he reported general malaise, feverishness, nocturnal headache, etc., and the first macules were found on the lateral portions of the trunk. By June 3d the eruption had come out profusely over the trunk and extremities.

Since that date the patient has been kept under treatment, but in a more or less irregular manner. Under inunctions the macular eruption disappeared, and, as mentioned, the sores on penis healed; but in August he returned with a papular syphilide on the tongue and lips and ad anum, severe alopecia, and cephalalgia. More lately a grouped small papular eruption has appeared on the body and extremities, and an ulcerating lesion in the mouth on the inside of the cheek.

The interest in this otherwise typical case of syphilis is due to the multiplicity of the initial lesions. The belief generally entertained is that the initial lesions of the disease are single, as distinguished from chancroids, which are usually multiple.

Those writers, however, who have had large clinical experience, claim that multiple chancres are not of such very infrequent occurrence. Mauriac, for instance, states that they are as often multiple as simple, and that he has seen as many as fourteen to sixteen on the same individual. Whether other observers have had the same experience or not, the fact, however, that the primary sores of syphilis may be more than one in number is of considerable importance. Oftentimes the prognosis given to an individual will be much more guarded, and he be not assured that the sores contracted from a suspicious connection are not syphilis, because multiple, when it is borne in mind that there may be not one alone, but several initial lesions ushering in that disease, and the physician will also be saved from some awkward moments if, after having quieted the patient by telling him his trouble is only a local one, he is, a few weeks later, confronted by a macular eruption and other symptoms of a general infection. Perhaps the best criterion by which to judge a sore is the time which has elapsed between its appearance and the suspicious connection. The period of incubation of the local disease—chancroid—is usually from three to five days, that of the syphilitic chancre from two to three weeks.

Still this latter has been known to appear in eight to ten days after infection, and when, in addition, it so often happens that patients state that they do not remember the last time they had connection, or they have had repeatedly relations with women up to the time of the appearance of the sores on the penis or elsewhere, it is evident that in a doubtful case any opinion expressed should be a conservative one. Another misleading circumstance is that the poison of both chancroids and of syphilis may have been inoculated at the same time and at the same point, possibly several of the former appearing in a few days, the latter only perhaps some weeks later and after the others have healed entirely. As long as such elements of error in diagnosis and prognosis exist,

it is certainly wiser to wait in such cases for further symptoms before committing one's self absolutely. If the sores are syphilitic, the diagnosis is soon made apparent by the indolent enlargement of the lymphatic glands in proximity to them, followed by gradual and general adenitis, by the early eruptions, etc., factors absent and not appearing if the contrary is the case. A case in my private practice in 1889 illustrated very well this point of multiplicity of syphilitic primary lesions and the want of a history of the infection. The patient, a man of education and intelligence, presented himself with eight distinct small scleroses on the glans penis and prepuce. There was practically no history, as he had had repeated connections with various women up to a week previously. He had first noticed the sores the day after the last connection, and regarding them as chancroids had been treating them with lotio nigra, as he had done at previous times, when he had had such sores. He was quite conversant with syphilis, having read a good deal about it and also acquired information from physicians concerning it, and absolutely scouted and laughed at the idea that the sores could be specific ones, for the sole reason that *they were multiple*. A week later, however, indolent enlargement of the glands in both inguinal regions began, and at the end of four to five weeks the existence of general adenitis, the usual initiatory symptoms of the disease, and a profuse macular eruption, convinced him that the original diagnosis had been a correct one.

As far as the case reported in this article is concerned, it presented an interesting feature in addition to the multiplicity of the initial sores, in that these latter did not appear simultaneously but at intervals of a few days. Mauriac states that as a rule they appear at the same time, but occasionally they may appear successively, and he cites a case of his own in which the interval between two syphilitic initial lesions was seven days. In the case of Benjamin A—— , his own statement and observation were the only data by which the question could be judged, and, in consequence, the exact interval of time between the appearance of each chancre must be taken as only approximately correct. Inaccuracy in the statements obtained from patients is usually the case, so that it would be best in this instance to conclude that there was a certain interval of time between the first and fourth chancre, without, however, definitely specifying how long it was. In the other patient referred to here, in all probability the chancres appeared simultaneously, as they were all present when seen by him; and in still a third case, seen by me in consultation with Dr. R. B. Kimball, in 1887, and in which there were three chancres, the same simultaneous outbreak had occurred.

The sores which were situated on the penis of Benjamin A—— could not be considered as any other form of lesion than as syphilitic chancres. They presented markedly the symptoms characteristic of these lesions, and the subsequent glandular development, etc., as well as the macular eruption later, substantiated that fact. Their entire involution did not occur until after the patient had been put upon specific treatment, and only on the sites of the first and second, those which had ulcerated, did any scars remain after they were healed. These facts are mentioned again, owing to the possibility of the lesions which he had had in February being considered as the infecting ones. They were, however, typical local, non-infecting sores, and were not followed by glandular implication or any other symptoms. Three and a half months' duration of the secondary period of incubation, though not impossible, is yet a very unusual and rare occurrence, but an interval of time of a little more than three months between the appearance of the primary lesions and glandular enlargement is out of the question.

Case III. *Lymphangioma Circumscriptum.*—The patient, a boy, aged twelve, was brought to my office in August of last year. He was well grown and in normal physical health. The father, who accompanied him, stated that the primary evidence of the disease was noticed on the first phalanx of the great toe shortly after birth. At the age of six, further lesions developed about the middle of the leg, and since then new ones have appeared all the way up to the middle third of the thigh. They have not remained unchanged from the time of their first appearance, but have undergone involution and evolution. The boy has been under treatment almost all the time, has received internal remedies and local applications of all kinds and sorts, and lately destruction of the patches by means of the actual cautery has been attempted.

On examining the boy, it was immediately noticed that the right lower extremity, the seat of the lesions, was smaller in circumference than the left one, and it was said to be weak and not of as much service as the latter. It was also observed that the veins of the right leg and thigh, especially those on their extensor surfaces, were markedly varicose, as were also the circumflex iliac, the pubic, and the epigastric veins. Those on the left side did not show any abnormal changes. It could not be definitely ascertained how long this varicose enlargement of the veins had existed. When the boy was lying down, the symptoms were not very marked, but as soon as he stood up, the veins became large and prominent. There was no glandular enlargement below or about Poupart's ligament, and nothing could be made out, by palpation in the right iliac region, which could suggest obstruction to the circulation as the cause of the varicose condition of the veins on that side.

The cutaneous lesions were arranged quite regularly in the course and over the varicose vessels. For instance, there were a number of groups of individual lesions distributed linearly over one large vein, which, beginning at the middle and outer side of the leg, ran upward to the thigh in its course, curving around the external aspect of the knee. Similar accordance in situation between the groups and the veins was seen also to be almost the rule in this case, though some of the former occurred independently of the latter. The lesions occurred in groups for the most part, the individual ones being discrete, and coalescence of two or more did not seem to take place during their existence. The clusters consisted of a few, fifteen to thirty or more, separate, deep-seated, vesicular elevations, the size of an ordinary pinhead. There was no halo or zone of redness around those which had not been injured or irritated, but each lesion seemed to be seated upon normal skin. A few teleangiectatic vessels were seen coursing around the groups. The contents of these vesicles were clear and slightly yellowish, but if opened, the fluid which escaped quickly became tinged with blood. When a group had been subjected to rubbing or injury of some kind, evidences of inflammatory reaction developed about it, and the contents of the individual lesions became slightly mixed with blood or entirely replaced by the latter. No crusts were seen and nothing suggestive of them.

In addition to these superficial manifestations, there were found on the first phalanx of the great toe, where the disease had begun, and also alongside of the tendon of the semitendinosus muscle, a bunch of tortuous vessels about as large as a walnut, situated in the subcutaneous tissue, and being in all probability cavernous lymphangiomata. A number of scars on the leg attested to the use of the cautery in the treatment of the case, and around the margins of these new vesicular lesions had begun to appear. Unfortunately, permission to excise a lesion could not be obtained.

This case of rare cutaneous disease has been judged to be a representative of the lymphangioma circumscriptum, as described by Dr. Malcolm Morris,[1] owing to its strict symptomatic agreement with the example so superbly depicted by him, and also with the few others recorded in literature. Crocker treats of it under the name of lymphangiectodes, and states that all the cases he knows of began in early childhood, and occurred more

[1] International Atlas of Rare Skin Diseases, No. 1, 1889.

often among males than among females. A very thorough review of the subject has also lately been made by Finch, Noyes, and Lörok. From the histological study of the lesions they arrived at the conclusion that the nature of the process consisted in a proliferation of the angioblastema, in a new-growth of lymphatic vessels, and to a certain extent of blood vessels, and their transformation into cavities and broad channels. They believe that these cases represent varicose capillary lymphangiomata and hæmato-lymphangiomata.

Lymphangioma circumscriptum has been seen complicated with other diseases. Tilbury Fox's case had also a venous nævus, and one of Köbner was associated with cavernous angioma, lymphangioma, and neurofibroma, so that in my own case the presence of the varicose veins and deep-seated lymphangiomata are not exceptional complications. The existence of the varicose veins in so young a subject is, however, most unusual and difficult of explanation. Neither œdema of the foot or leg existed, indicative of venous obstruction of a decided character, nor could anything be made out at Poupart's ligament, or in the iliac fossa, suggesting such obstruction. On the contrary, the affected extremity was noticeably smaller than the left one; there were no enlarged glands, and in fact, nothing that could be regarded as mechanically inducing the venous dilatation. It may be that there had been at some time a chronic progressive phlebitis resulting in the varicose condition of the veins, or it might be that obstruction to the free passage of the blood was due to the external iliac vein being congenitally too small in calibre. Both of these are possibilities, but there was, however, nothing demonstrating the former, and the patient being still alive, proof of the latter could not be obtained. The arrangement of the groups of lesions over the varicose veins likewise suggests some connection or relationship between them, but in the absence of microscopical examination I am, however, not in a position to draw any conclusions in regard to the possible interdependence or relation of the two phenomena.

As far as the treatment of lymphangioma circumscriptum is concerned, little can be said. Some of the lesions disappear spontaneously, but return later. Destruction by means of caustics has been practised, but lesions have returned near the cicatrix. In my case, new vesicular elevations were seen around and about the scars produced before I saw him by the use of the Paquelin cautery. A rubber bandage had also been worn for a long time without any benefit to the boy. I tried electrolysis. It was followed by disappearance of a number of lesions besides the ones which had been pricked by the needle. Whether the result was a permanent one or not I cannot say, as, owing to the doubtful prognosis given, the patient remained under treatment only a short time.

Case IV. *Dermatitis Gangrænosa Infantum.*—Hannah J——, aged nineteen months, was seen by me March 6, 1889. She was anæmic and also suffered from a stomatitis aphthosa. The movements from the bowels had been loose, offensive, and greenish before the eruption began, but had become natural again. The cutaneous lesions had first appeared on the vulva one week before I saw the patient, and they had since then cropped out on the inner surfaces of the thighs, on the mons veneris and buttocks. On these portions were lesions in all stages of development. The primary ones were vesicles the size of a pea, surrounded by a dusky-red areola. In their course they increased rapidly in size, their contents became purulent, umbilication in their centres ensued, and then formation of a crust surrounded by an inflammatory areola. Further enlargement of the lesion continued, and in the largest ones—fully an inch in diameter—the crust was depressed and surrounded by an elevated and indurated deep-red border. On removing the crust, which was quite adherent, an extensive loss of tissue was found, the ulceration extending through the entire cutis to the subcutaneous connective tissue. In some the crusts rested upon a grayish mass of necrotic tissue saturated with an ichorous thin fluid, while in others the tissue seemed to have melted away and to be replaced by quite thick, purulent matter. The patient was given the iodide of iron and cod-liver oil, a weak bichloride of mercury mouth wash, and locally, an ointment of ichthyol (five per cent.) was to be applied after the crusts had been removed. On March 20th, all the lesions were completely healed, only scars remaining where the ulcerations had been.

The quite rare disease of the skin, of which this case is an example, has been described under various names. Varicella gangrænosa (Hutchinson), ecthyma infantile gangréneux (Pineau), pemphigus gangrænosus (Stokes), etc., besides the designation given by Crocker and used by me. It would seem also to agree quite closely with the ecthyma infantile or térébrant of the French. The disease develops secondarily to varicella, or vaccinia, or after measles, etc., and also spontaneously, and occurs in infants and young children. There may be severe constitutional symptoms accompanying it, fever even as high as 104° F., diarrhœa, albuminuria, etc., or there may be only slight systemic disturbances. Mild and protracted cases are met with, and also fatal ones. When the process appears after varicella, it usually begins on the head and upper part of the body (Crocker), but under other circumstances on the buttocks and lower half of the patient. Bacteriological investigation has demonstrated the presence of the streptococcus pyogenes as well as of others. The condition of the patient undoubtedly has also much to do with the appearance of the process.

In the case reported by me, as well as in two others which I have had and which were precisely similar, there were antecedent to the appearance of the lesions neither varicella nor vaccinia, nor any other eruptive disease, but the process originated spontaneously. All three cases occurred in female infants who were anæmic and run down, who had had intestinal troubles and diarrhœa preceding the appearance of the eruption. In all three the lesions were situated on the buttocks and thighs, and on portions of the body covered by the soiled napkins, and were in a class of patients with whom attention to cleanliness is not a virtue. This limitation of the process suggests very strongly that the source of the infection should be sought in the diarrhœal discharges preceding the appearance of the eruption, but yet it cannot be stated as a fact, for the reasons that the presence of the pathogenic cause in the movements from the bowels and its existence in the lesions was not determined, nor was it demonstrated that these latter were the effect of the former. Consequently the possibility of the two conditions being interrelated is mentioned only as a suggestive explanation of the origin of the disease in these cases. It does not seem as though this form of cutaneous disease could be confounded with any other, though possibly syphilis would be thought of by those unfamiliar with this latter. But even a moderate degree of observation and care ought to prevent such an error being made. Still the case reported here had been diagnosed as syphilis before it came to me, and had been treated with iodide of potash internally. The rapid course of a lesion and its various metamorphoses from a bullous to one filled with pus, then drying into a scab in the centre, underneath which deep ulceration and gangrenous destruction of tissue occur, form, however, a group of cutaneous symptoms which could only by carelessness be ascribed to syphilis.

The treatment of this disease of the skin should be both local and general. The latter must naturally be a symptomatic one and in accordance with the indications existing. That is, proper food, tonics, etc., should be given if necessary, the alimentary canal put into proper healthy condition, the child be given stimulants, sedatives, etc., according as necessity arises for their use. Locally, strict cleanliness must be enjoined and every means taken to obtain it; the lesions themselves, as well as the skin around them, ought to be treated antiseptically. Iodoform, iodol, chlorinated soda, boric acid, have all been

recommended, but I found ichthyol to give the most rapid and best results. In my three cases, the skin of the portions of the body affected was thoroughly washed with a solution of $HgCl_2$ (1 to 5,000), and when dry, not the lesions alone, but the entire surface on which they were situated, was covered with the ichthyol ointment spread on strips of canton flannel. Over these oiled silk was laid and the whole kept in place by gauze bandages. It was sought by these means to protect the surface from the fecal discharges and the urine, and also to limit the possibility of auto-inoculation, and the result obtained was that no new lesions appeared after the first dressing, and that those already existing healed rapidly. The local treatment would appear to be the *sine qua non*, the internal one being only an adjuvant, and consequently the former should receive the more careful attention.

Case V. *Relapsing Desquamative Erythema.*—A. D——, aged twenty-nine, a solderer by trade, consulted me at my office, March 15, 1890, for a recurrent affection of the palms and soles. The first attack occurred in May, 1886, but at that time the entire body was universally affected. The cutaneous symptoms were preceded for several days by cephalalgia, and then by an intolerable itching of the chest and hands, which became diffusely reddened. Similar appearances developed rapidly in the form of patches on other portions of the body, the eruption became more diffuse and then confluent, so that the entire surface was of an intense red color, burning and itching unceasingly. The redness lasted three days, and on its disappearance the itching ceased and desquamation began. This took place in the form of flakes, squamæ and lamellæ of all sizes, and ran its course without any subjective sensations whatever. The second attack occurred also in May, 1887, and it, as well as all subsequent ones, were limited to the hands and feet. The third outbreak was in May, 1888, and again relapses in June of the same year. Freedom until February, 1890, when the eruptions returned, and still another attack in March, when he consulted me. All of these relapses had been preceded by severe headache for a few hours or as much as three days, costiveness, and the two occurring in 1890 had been ushered in by chills and febrile movement. He could not ascribe any cause for the outbreaks, as he was, with the exception of costiveness and some headaches, strong, well, and healthy. Previous to the last attack he had, however, been much excited. The symptoms, as far as the skin was concerned, were always the same. There would be an intense burning and itching sensation of the entire hands and feet, lasting for a few hours and followed by a bright redness. The redness and itching would remain for about three days, and then the color fading, desquamation would begin and be completed in a week or more. There were never any moist places or vesicular or other lesions, nor were the nails affected.

When seen by me in March, the hands and feet had already passed through the stage of redness, and that of exfoliation was present. There was not any true desquamation, but the epidermis was exfoliated in one piece from the entire affected surfaces. I removed as a whole the epidermis covering the palms and palmar surfaces of the fingers from the wrists to the tips of the latter, and if care had been taken the cuticle of the whole hand could have been stripped off like a glove. Underneath this exfoliated epidermis the skin was covered by a smooth and thin horny layer, one, however, completely normal in character. The patient, who lived quite a distance from the city, in Connecticut, informed me later by letter that his constipation was relieved, that he felt well, but that on March 21st another attack had set in. It had been precisely similar to the former ones, except that it had not been preceded by headaches, chills or fever, and had been limited to the hands alone. Absolutely no inducing or determining cause for the attack could be suggested.

Though this patient was not seen at the time the attack began, but only some days later, yet from the general description he gave of the symptoms, the course followed by the disease, and from the existing exfoliation of the epidermis, it was possible to recognize the affection as an example of relapsing scarlatiniform erythema. Most peculiar was it, however, that though the first attack was universal, yet the subsequent ones were limited to the hands and feet alone, a peculiarity which I can find manifested by only one other case recorded, as far as I have been able to discover. This one was reported in 1878 by Dr. Bulkley,[1] and it agreed closely with the instance recorded here by myself, except that the duration of the disease had been longer, and that the number of outbreaks had been greater.

Scarlatiniform erythema has been observed to make its appearance under the influence of divers demonstrable causes, as well as idiopathically and without traceable reason, to be limited to one attack, or to relapse any number of times. The conditions under which it may arise have been mentioned by me in an article which appeared in January, 1889,[2] and need not be enumerated here again. Under the action of some one cause or another or idiopathically, to repeat, the same eruption may appear, but yet the same agent is not necessary to always reproduce the cutaneous symptoms every time in the same individual, but they may arise under the influence of entirely distinct causes. The eruption may at times be more limited than at others, or be more diffuse and general, but yet in each attack the symptoms are substantially the same, no matter what may be the etiological or determining factor of the outbreak. In the case, for instance, which I reported (*loc. cit.*) in January, 1890, the symptoms and course were the same as in the one recorded here, though the former was much more diffuse and general; yet in the one the etiological cause was the abnormal condition and position respectively of the uterus and ovary, while in the other it appeared to be due to the influence of the seasons of the year, inasmuch as the first three attacks occurred in the month of May of the successive years, 1886, 1887 and 1888. In 1890 the relapse took place in February, and twice recurred in March, but during the entire time from the first attack to the last one, the patient was free from it except in the months named. The result of observation of these cases of relapsing erythema is that they have a tendency to recur more and more frequently in proportion to the duration of the disease, and to come at shorter intervals. It is possible, therefore, that in the end the annual type, or the recurrences at certain seasons of the year, may gradually become obscured. The course which this case appears to be following suggests that possibility, and it would not surprise me to see him return with another attack at a near date.

The recognition of scarlatiniform erythema, when it occurs in connection with septic processes, or with other systemic diseases, or from the administration of certain drugs, or from some one or other definite etiological cause, or even when idiopathic, should not be difficult. More often in the latter form the history of precedent attacks will be obtained, but when it is a first outbreak the differentiation between it and some mild cases of true scarlatina may offer some difficulty. When of limited extent, of course, it would be readily recognized, but if diffuse over the whole surface and with throat symptoms, possibility of confusion would certainly exist. Still, in scarlet fever there are marked general systemic symptoms preceding the eruption, the pyrexia is more intense and continued, there is decided implication of the throat, the strawberry tongue, and especially renal symptoms. The erythema may also be confused with other cutaneous diseases, but the scope of this article renders it unnecessary to refer to all of them.

The prognosis and treatment in the cases of scarlatiniform erythema will vary according to the etiological cause

[1] Archives of Dermatology, vol. iv., 1878.
[2] N. Y. Medical Journal, January 11, 1890.

in any given case. If merely the effect of some drug toward which the patient has an idiosyncrasy, cessation of its administration will often be followed by subsidence and disappearance of the eruption, until the drug is again ingested. Still cases have occurred in which the process has continued by a succession of relapses over a long period of time after the administration of the drug has been stopped, and without the latter having been taken again. If due to septic or pyæmic processes, or in the puerperal state, the appearance of the eruption usually presages a fatal result. In other words, the prognosis will vary in every case in accordance with the basic and inducing cause. In the cases which appear to be idiopathic in origin, the prognosis will certainly be a doubtful one, as it is impossible to foretell a relapse or to specify the number of these which may occur. Tilbury Fox mentions, for instance, a case in which there had been over a hundred recurrences of the eruption, and yet there was no certainty of when the next attack would appear. The treatment again will be guided by the same factors as the prognosis, and be directed against any possible cause which may be suspected or suggestive of playing a part in producing the eruption. It does not seem possible to cut an attack short, nor in many of the cases to prescribe any line of treatment which will prevent relapses; certainly not in those apparently developing without any cause, or brought about by circumstances or conditions which are not removable. When the eruption is present in these instances, symptomatic treatment is about all that can be made use of.

Case VI. *Chloasma in a Hypospadiac.*—Patient, aged thirty-five, came to my office in July of last year, in regard to a pigmentation which had appeared upon his face repeatedly and remained there steadily, except during the winter months. The patches were light or dark brown, symmetrical on the cheeks, on both wrists, and on the neck, and also in the middle of the forehead. The pigmentation began in front of the ears on the face and extended to about the middle of the cheeks on both sides, curving along the infra-orbital margin. Thence it descended in an irregular manner to the angles of the mouth, around which it passed to the chin, which it covered uniformly, leaving free, however, a space about one-third of an inch broad below the vermilion border of the lower lip. This patch was continuous with the pigmentation situated on the neck. The entire middle portion of the face was free. The patches on the wrists extended almost around them, and were so situated that they were always covered by the cuffs and sleeves of the coat. The localization, limitation, and situation of these patches excluded the possibility of their being simply sunburn, but allowed the diagnosis of chloasma to be made.

In the course of the examination of the lesions, the patient suggested that his heart be auscultated, as he suffered from palpitation. After taking off his shirt, it was noticed that, for a male, the mammary glands seemed to be unusually developed, in fact were as large as a woman's usually are, and on continuing the examination, the patient was found to present the following anomalies in his formation: It had already been observed that he was beardless, that the mammæ were large and gave the impression of being glandular tissue, not fat alone; but it was now seen that the hips were very broad, the thighs inclined inward, the legs slightly outward as in a woman. The mons veneris was very prominent and covered with hair, but a penis and scrotum was not present. In their place there was an opening situated between two redundant folds of skin, and in each of which a small testis could be felt. When these folds were well separated, a perfectly shaped glans penis of good size was seen some distance inside, occupying, relatively speaking, about the situation of the clitoris in the female. The patient stated that even when erected it never protruded externally. There was no meatus urinarius seen, but below the glans a canal several inches long led inward and upward. This passage was quite large and distensible, and at its upper end there could be felt a constricted firm portion, which was judged to be the sphincter and neck of the bladder. The patient stated that he had always urinated in a sitting posture, and that he could feel the urine running down this canal. He confessed to masturbation and said that when the orgasm occurred, there was an ejaculation of semen which dribbled down the passage. Labia minora, meatus urinarius, etc., as are found in women, there were no traces of. There had never been any suggestion of menstruation, nor any evidence obtained that even a rudimentary uterus or ovaries existed. In fact, the case was one of hypospadia in a marked degree. The patient stated that being excessively endowed with animal passions, his desire was oftentimes so intense as to cause him pain, and he obtained relief from masturbation; but that he had not infrequently dressed up as a woman and men had had sexual intercourse with him, under the impression that he was of the female sex. Under those circumstances, he stated that the pleasurable sensations he experienced were intense. Possibly he was telling the truth, and to judge by the canal and its size, as well as by the general conformation of the patient, the error of taking him for a woman would not be impossible, if, as he said, he was always careful to "entertain company" in a dimly-lighted room.

7 West Thirty-first Street.

THE TREATMENT OF AN ACUTE ATTACK OF HAY FEVER.

By ISIDOR GLUCK, M.D.,

Oculist and Aurist to the Academy of the Sacred Heart and Brownell Hall, Omaha, Neb.

Most of the modern writers on the subject of hay fever are inclined toward the view that the disease is a local affection of the mucous membrane and underlying tissue of the nose; that subjects thus affected are of neurotic temperament, and that for the production of an attack of hay fever an external irritation is essential.

Thus Daly, of Pittsburg, 1882, attributes the annually recurring attacks "to local chronic disease, upon which the exciting cause acts with effect."

Rose, of Rochester, N. Y., 1883, expresses the same view, holding that "hyperæsthesia is associated with, or occasioned by, a diseased condition, either latent or active, of the naso-pharyngeal mucous membrane."

Harrison Allen, of Philadelphia, 1884, in an article on the treatment of hay fever says, that the disease is caused by a permanent or temporary obstruction of one or both chambers.

Later in the same year, J. N. Mackenzie, of Baltimore, suggesting the term "coryza-vaso-motoria periodica," on the ground of the decided tendency to periodic recurrence, holds that for the production of a paroxysm a certain excitability of the nasal cavernous tissue is necessary; that there exists in the nose a well defined sensitive area, whose stimulation through a local pathological process, or through an ab-extra irritation is capable of producing an excitation, which finds its expression in a reflex act, a series of reflected phenomena.

Sajous, in his "Lectures on the Diseases of the Nose and Throat," 1886, page 180, says, that in hay-fever patients an hyperæsthetic state of the mucous membrane, either latent or due to local disease, is always present, and the condition of the mucous membrane is an essential factor in the reproduction of an attack.

Bosworth, in the *New York Medical Journal*, May 1st of the same year, argued that the prominent predisposing cause of all cases of hay fever was an obstructive lesion in the nose, and that for the production of the disease three conditions were essential: 1, An obstructive lesion of the nose; 2, neurotic habit; 3, the impact of pollen upon the nasal mucous membrane.

Andrew Clark, in 1887, published a paper on the same subject, pursuing much the same line of argument as Bosworth, giving, as most of the modern writers, as require-

ments for the production of the disease. three conditions : 1, Neurotic habit; 2, an intra-nasal pathological condition; 3, an external exciting cause.

After reviewing the different statements and arguments in regard to the cause and production of hay fever, and also giving some consideration to my own observations, I venture to state that there are only two conditions necessary for the production of hay fever : 1, A characteristic intra-nasal pathological condition ; 2, an external cause.

My reason for omitting a third condition, the neurotic habit, is, that from my own observation, and from cases on record, I am inclined to the belief that the neurotic habit in most all cases is a product of the disease, and its manifestations in direct proportion to the severity of the attack and length of time the patient has been subjected to it.

That hay fever is pre-eminently a local disease can also be claimed by the fact that therapeutics applied for the improvement of the constitution and nervous system have failed to influence the force and character of the disease, whereas local treatment to the affected parts produces the desired effect.

Since 1888 I have employed a solution of sulphate of atropia locally for the treatment of acute attacks of hay fever, and from the thirteen cases I had under treatment, and from the records I present you, it becomes evident than in most cases an acute attack" can be aborted in from two to five days. One rarely encounters a case in which the drug fails to act as expected. It might occur in an individual of extraordinary susceptibility to atropia. In such cases tolerance is very easily established, but at the cost of the therapeutical effect, which is reduced, if not entirely lost.

Sulphate of atropia, when locally applied to the nasal mucous membrane, acts as a depressant, as a local sedative upon the end fibres of the sensory nerves. It also affects the vaso-motor and afferent nerves. It causes contraction of the arterioles, relieves and prevents reflex phenomena such as paroxysmal sneezing. It depresses the activity of the glandular elements and thus diminishes the secretion of an exudate, which, being of an irritating character, causes the violent paroxysmal sneezing and other reflex phenomena often found associated with hay fever.

Absorption from the mucous membrane of the nose being very rapid, the first physiological effect from a local application in children and young adults will manifest itself in from five to seven minutes, and will disappear in from thirty to forty minutes. In adults the effect lasts much longer, drowsiness may last for hours. The mode of treatment employed in the cases recorded was as follows :

Realizing that any irritation will aggravate an attack, I avoided all sprays. I dipped a piece of absorbent cotton, attached to a cotton holder, in a solution of cocaine-phenol, formula of which I published in the MEDICAL RECORD, New York, June 20, 1890, and applied the solution to the engorged parts. After some contraction and moderate amount of anæsthesia had been produced I applied, in the same manner, a one per cent. solution of sulphate of atropia. Internally I prescribed small doses of aconitine every hour or two, according to the severity of the case. Next day patients were invariably better. I continued same treatment until recovery. In addition to the local treatment, I am in the habit of prescribing a tonic containing phosphate of iron and quinine.

Cocaine-phenol is especially advantageous in the treatment of hay fever. But a cocaine solution applied without the phenol will cause irritation and sneezing, which lasts until the first effect of the anæsthesia sets in ; whereas the phenol, the very moment it is applied, produces anæsthesia to a certain degree, sufficient to counteract the irritation produced by the application.

I give the history of the patients I have had under treatment, in a condensed form, and wish to remark that where I have omitted to state whether any members of the same families have had the same affection, it is to be assumed that there were none thus affected. Most of the patients complain of a peculiar tickling sensation of the palate and catarrhal conjunctivitis. Every patient has had the mumps.

CASE I. (April 10, 1888.)—Mrs. D——, aged fifty, has been subject to hay fever for sixteen years. Attack comes about August 20th. She came to consult me on account of deafness; R. ear, 1½ inch ; L. ear, 3 inches, with watch test. I cauterized hypertrophy of the nose in order to restore hearing and prevent recurrence of hay fever. Discharged her, with hearing in R. ear 12 inches, L. ear 14 inches. Remained free from hay fever the entire season.

August 24, 1889.—Not the slightest indication of an attack ; having passed the usual day of recurrence she left the city for a few days, returning September 3d, stating that as soon as she entered the cars and inhaled the smoke she had an attack of hay fever and was still suffering, although not very much. I applied cocaine and phenol, and then atropia, as described above, entirely relieving her. She has been well since.

October 20, 1890.—No attack this year; had been exceptionally well, gained in flesh, and is very much improved in every respect.

CASE II. (June 9, 1888.)—Mr. D. J. C——, aged twenty-seven, presents the following history : Had hay fever when a baby, before he was able to walk, and has been attacked every year since. His paroxysms generally commence on May 24th. His brother and sister are also subject to hay fever. Their attacks come on in August. Examined patient and diagnosed membranous rhinitis. Treatment very much the same as for hay fever. Next day he brought me for inspection two large pieces of membrane he had blown from his nose a few hours after treatment. Continued treatment on the 10th, 11th, and 13th. Patient well. I suggested cauterization, but he would not consent to it.

September 1st.—Slight attack of hay fever. Treatment given. Left office very much relieved and has remained well since.

June 9, 1889.—Hay fever attack came on May 14th. Treatment 14th, 15th, 18th, 20th, and 24th. Well, and remained so until

June 5, 1890.—Awoke on that morning with all of the symptoms of hay fever. Treatment the 5th, 6th, 7th, and 9th. Well.

On the 22d of June exposed himself to the rain, became thoroughly wet, and had, on the next day, all of the manifestations of hay fever. Treatment on the 23d, 26th, and 27th. Patient cured and remained so during the entire season.

CASE III. (August 1, 1888.)—Mr. M. H. R——, aged twenty-nine. Hay fever for five years. Attack comes on in July, no definite date. Treatment on the 1st, 2d, 3d, and 4th. Patient well. Saw him last in September, before his removal from the city. Have not heard from him since.

CASE IV. (August 23, 1888.)—Mr. O——, aged thirty-eight. Has had hay fever for twelve years. Comes on first part of August. Only the left nostril is affected. Treatment on the 23d and 24th. Patient well. I suggested cauterization for possible permanent relief. On the 27th I commenced cauterization.

August, 1889.—Met him, and he passingly remarked that he thought he had a slight touch of the old trouble, but not sufficient to apply for treatment. Have not seen him since.

CASE V. (August 27, 1888.)—Master T——, aged twelve. Has had very bad colds for the last two years, causing paroxysms of sneezing. Eyes injected. Complains of tickling of the roof of the mouth. He is nervous and very restless. His hearing is impaired. Diagnosed hay fever. Treatment on the 27th, 28th, and 29th. All symptoms before described disappeared. Impairment of hearing remained. I advised cauterization, which I commenced October 2d. Hearing has not improved, having cauterized four times in six weeks.

Case VI. (September 4, 1888.)—Miss M——, aged twenty two. Has had hay fever for ten years, bronchitis, and paroxysmal cough. Lung trouble in the family. Mother and one sister died of phthisis. Attack comes on sometimes in June. July, or August. Treatment on the 4th, 5th, 6th, and 7th. Treatment for the cough, one-sixth grain of codeine every fifteen minutes until relieved. Generally six to eight doses arrest the cough. I advised cauterization, to which she consented.

1889.—Spent summer in Europe.

1890.—Had no attack.

Case VII. (September 25, 1888.)—Mr. H——, aged twenty-seven. Has had hay fever since 1883. The attack comes on between the 15th and 25th of August: this year on the 1st of August. Treatment on the 25th, 26th, 27th, 28th, 29th, 30th, and 31st. Well. Patient is a newspaper reporter. During fair-week he was continually exposing himself to dust and heat. During the day, in consequence of the treatment, he has felt perfectly comfortable and had no paroxysms, but on awaking in the morning he was subject to violent sneezing. At the end of the week he changed his occupation, and he has continued well. He left city in January, and I have not heard from him since.

Case VIII. (September 27, 1888.)—Mr. C. G——, aged forty-four. Has been subject to attacks of hay fever for nine years. Treatment on the 27th, 28th, 29th, and 30th. Well. Saw him October 5th, before he had left the city. On his journey he had some slight attacks, which since his arrival in Chicago have not recurred. Was free from all attacks that season. Have not heard from him since.

Case IX. (August 7, 1889.)—Mr. L——, aged thirty-nine. Hay fever of ten years' standing. Attacks come on irregularly in June or July. The paroxysms vary in severity during season and during the day. After a hearty meal he is generally worse. Treatment on the 7th and 8th. Well. Saw him last on the 22d of August; he has been free from an attack since his last treatment on the 8th. Have not heard from him since.

Case X. (September 8, 1889.)—G. W——, aged forty-one. Hay-fever of four years' standing. Attack comes on during some seasons in August and during other seasons in September. Treatment on the 8th, 9th, 10th, and 11th. Well. Commenced cauterization on the 14th.

November, 1890.—Has had no attack this year, and none since his treatment on the 11th of September of last year.

Case XI. (June 5, 1889.)—Mrs. P——, aged thirty-four. Has had hay fever for four years. Treatment on the 5th, 7th, 10th, and 11th. I saw her on the 17th, and she stated that since the last day of treatment she had been well. She left the city for the East the 18th. Later she informed me that during her voyage she had very severe attacks, and that she attributed the severity of the same to the treatment. Have not seen her since.

Case XII. (August 26, 1889.)—Mrs. R——, aged twenty-eight. Hay fever of six years' standing; attacked generally in June. Her mother and mother's sister also have hay fever. The presence of fresh fruit will produce a paroxysm. Two years ago some one lighted a sulphur match in her presence, and the fumes gave her an attack of asthma. Since then she is also occasionally subject to asthma. She is very susceptible to quinine; five grains will bring on an attack of asthma. Treatment August 26th and 27th. Well. August 31st she had an attack of asthma. I prescribed sodium nitrite, gr. $\frac{1}{6}$, every fifteen minutes until relieved. Six doses have freed her from all symptoms. Later I cauterized hypertrophies in the nose, and she had no return of hay fever or asthma until

April 1, 1890, when she had taken for the relief of a cold fifteen grains of quinine, which produced the most severe attack of asthma I ever saw, potassium iod., gr. 20, completely relieved her.

November.—Had no attack of hay fever since August 7, 1889.

Case XIII. (August 15, 1890.)—Mrs. J. M. B——, aged thirty. Has had hay fever for fifteen years. Has generally two attacks in same year; one in spring, coming on with the first blossoms, and lasts for three or four weeks. Second attack comes on about August 16th. This year it came on August 1st.

The odor of perfume, also stale flowers, have produced attacks. She is very susceptible to morphine. She states that one-sixth of a grain will put her to sleep for twenty-four hours. Treatment the 15th. Hardly three minutes had elapsed after the application of atropia when her face became intensely red. About ten minutes later she complained of intense dryness of throat. Next day she informed me that she was much improved, and that she had only one very slight paroxysm. Treatment the 16th. The 17th I did not see her. The 18th she applied for treatment again, stating that, having felt perfectly well, she went the previous morning to a picnic, remained out doors all day without the slighest sign of an attack. On awaking this morning she had a severe attack. I applied the atropia without producing flushing of the face. She received treatment for six days longer, but no matter how freely I applied the atropia I could produce no satisfactory result. The patient having been exceedingly susceptible to the drug, has acquired tolerance at the expense of the therapeutical effect, which was slight. Such cases are, fortunately, very rare.

One of the peculiarities of this affection is, as universally claimed, that the attack comes on almost always on the same day of each year; and some patients are even positive of the hour of its regular appearance. From the thirteen cases cited there is, with the exception of one (Case II.), none who could state the day with certainty. As to Case II., I met him this year shortly before his usual attack was to come on, and made a remark to that effect. "Oh! no," he answered, "the Queen's birthday is the day for my attacks." The Queen has her birthdays regularly on May 24th; but, as his record shows, he had not his attacks on those days. He always had them later, and at different times. This tends to show how unreliable such statements are. I do not deny that there are individuals who notice symptoms of the affection every year on the same day, but I am inclined to believe that mental influence and anticipation play a great rôle in the prompt appearance of such symptoms. The very same gentleman gives me cause for some other remarks, which I desire to make in this connection.

June 9, 1888, he consulted me in regard to his hay fever, from which he was, as he stated, that very day suffering. Examination revealed membranous rhinitis. Both affections are so similar in their manifestations that it requires a very careful examination in order to differentiate. When there is a membrane present the diagnosis is easy. In cases where no membrane has yet formed, cocaine will aid in the diagnosis. Here a cocaine solution applied to the engorged parts will produce anæsthesia, but not contraction. In hay fever it will produce both. This case shows that a patient might have hay fever for years, and during the approach of the season acquire membranous rhinitis, which will take the place of his annual attack.

It is likely that both affections are closely allied; more so as the treatment for both are the same, and the duration and effect of treatment the same. We apply atropia to check exudation, and we check the disease. It is likely that the glandular elements of the nose, by some irritating influence, secrete an exudate chemically different in quality from the exudate in hay fever, which, when coming in contact with air, will coagulate and form the membrane.

Whether any disease peculiar to childhood has any influence upon the production of hay fever, was suggested to my mind by the fact that all of the thirteen cases I had under treatment have had the mumps. But Case XIII. had hay fever two years before she had the mumps, and as she is very positive of this fact, a conclusion would not be warranted.

SUCCESSFUL EFFORT TO RESTORE BINOCULAR VISION BY A PARTIAL TENOTOMY OF THE SUPERIOR RECTUS.

By RICHARD H. DERBY, M.D.,
SURGEON NEW YORK EYE AND EAR INFIRMARY.

THE following cases are worthy of publication as illustrating the value of orthoptic treatment of the eyes, both before and after having recourse to surgical measures. In both of these cases the value of prismatic glasses was amply demonstrated before the tenotomy was made, and in both the restoration of comfortable binocular vision was secured by the operation.

Elinor H——, girl, aged twelve, came to me April 18, 1888. The mother gave the following account of the case: "From the time Elinor, as a baby, began really to look at any object, her head was always inclined to the right of the upright. Following our physician's advice we regarded it as a childish trick, and were always careful to place her toys, etc., to the left rather than the right side. This had no effect, and soon the child began raising the right brow and fixing the right eye into rather a strained look. This habit increased, and the distortion of countenance became very distressing. Her head began to give her a great deal of trouble, and looking back now I see that these symptoms increased as she began to read. She never complained of any trouble with her eyes, but I have seen that the child was gradually learning to hold her book nearer to her eyes, and that she saw less well objects at a distance. She became nervous, and at times she complained (with marked terror) of everything growing so large to her."

This was in substance the condition of the patient when she came under treatment. There was of the right eye a myopia of 2 D., of the left, of 1.25 D. The vision of each eye was more than .6. There was insufficiency of the interni of 10°, and of the left superior rectus of 8°. The patient was directed to wear the following glasses: Right eye, prism 8° (base up), and left eye, prism 10° (base in), and to wear this continuously. Of the effect of the glass the mother stated: "She lost after a few days the worn look, and while still a very nervous, irritable child, she gained decidedly in her physical endurance; she read without headache and slept well, more quietly than before using her glasses."

The mother was directed daily to test the eyes for diplopia, using a candle and a piece of red glass before one eye, and the child was made to use the stereoscope with Green's cards. A careful record was kept by the mother, and from her notes I take the following: "I have found the greatest departure from single vision to occur in the morning test. Any fatigue, excitement, or physical disturbance will produce double vision. The change of place in the lines of a book has ceased to trouble her, and she can sight a small air-gun now, which she never could before."

During the summer patient continued to wear with relief the prismatic glasses. On October 22d a tenotomy of the rectus externus of the left eye was made without a suture, and patient was given for the right eye a prism of 4° (base up), and for the left a prism of 4° (base down). On October 31st the glasses were changed for the following: Right eye, — 2.5 D.; left eye, — 1.25 D., combined with prism 4° (base down). This glass was worn habitually, and with it there was at no time diplopia.

December 31st a partial tenotomy of the superior rectus of the left eye, leaving a small bundle of the inner fibres intact, was made. Directly after the operation the left eye stood lower by 2° for candle held on horizontal plane at distance of 3 m.

January 2, 1889, the tests, both with red glass and with the stereoscope, show binocular single vision, and this without any concave or prismatic glass whatever. The ophthalmometer shows no corneal astigmatism. At the present time, December, 1890, patient gives no evidence of disturbance of the muscular equilibrium of the eyes.

The second case, M. S——, a man, aged thirty, came to me April 2, 1888. Two weeks before, while riding, he was struck by the flat of his horse's head in the left eye. For two days after the injury the eye was closed. After that there was double sight. When patient was seen there was a cicatrix fully an inch long running from the middle of the left eyebrow downward and outward, following the margin of the orbit. The eyes were emmetropic, and the vision of each was normal. There was crossed diplopia, and the image of the left eye stood below that of the right. The vertical diplopia increased as the eyes were directed downward. Above the horizontal meridian there was single vision. A prism of 12° (base in) before the right eye, and prism of 20° (base down) before the left, nearly corrects diplopia for objects held two to three metres away. Patient received the following glasses: Right eye, prism 10° (base in), and left eye, prism 20° (base down). These glasses patient wore for one week with complete relief. Patient was gradually given weaker and weaker prisms until, for daily use, he wore before the left eye a prism of 5° (base down), and before the right eye a plane glass.

In March, 1889, nearly a year after the injury, patient returned complaining of occasional diplopia and pain in his left eye. With a candle on the floor before patient (seated) the diplopia is corrected by (right eye) prism 5° (base in), and left eye, prism 4° (base down). Patient received for right eye, prism 4° (base at 35°), and the use of this relieved his ocular symptoms. With a view now to subsequent tenotomy of the left superior rectus patient received at intervals of three to four days a successively stronger prism to wear before the right eye, until, on May 21, 1889, he wore with comfort (right eye) prism 10° (base at 35°). May 22d, under cocaine, a partial tenotomy of the left superior rectus was made, leaving a small bundle of fibres uncut inward.

Directly after the operation there was lateral equilibrium and a difference in height of the images of less than 2°. The next day diplopia could be produced only at a point 35° above the horizon. Since the operation patient has not complained of asthenopic symptoms or of double vision.

Progress of Medical Science.

Ligature of the Saphena Vein in Cases of Varicose Veins.— Professor Trendelenburg advocates double ligature and division of the large saphena vein in the treatment of varicosity of the lower limb involving both the trunk and branches of this vessel (*The British Medical Journal*). In some remarks on the pathological anatomy of varicose veins it is pointed out that the most prominent and dilated portions of the affected vessel are found below, and not, as is generally supposed, above the valves. The walls of the vein, being weaker here than at other points, yield most readily to the pressure of the blood when the valves cease to act. According to Trendelenburg, most of the blood which fills the dilated trunk and branches of a varicose saphena vein is derived from above, and has descended from the iliac veins and the vena cava, and but a small portion of it comes from the capillaries of the foot and leg. When the subject of varicose vein exchanges the horizontal for the vertical position a large quantity of blood at once descends from the large veins of the abdomen into the dilated veins of the lower extremity. It is this free downward flow of blood along large and dilated vessels deprived of valves that causes the profuse and dangerous hemorrhage so frequently produced by a breach of the surface of the leg when in a condition of varicosity. The conclusion that the troubles and dangers of those suffering from varicose veins of the lower limb are due for the most part

to the fact that the varicose branches of the great saphena, in consequence of associated dilatation of the trunk of this vein, are no longer separated from the vena cava by valves, has led Trendelenburg to treat varicosity by permanently obstructing the saphenous trunk at one point, with the view of preventing the descent of blood from the abdomen, and thus relieving the veins of the leg and foot from the abnormal pressure. After obstruction of the flow of blood through the main trunk of the great saphena, the venous circulation will be maintained by communicating branches between the superficial and deep veins. Reference is made to a series of cases in which good results followed such treatment, which consists in exposure of the vein near the saphenous opening, in the application of two catgut ligatures, and in the division between these of the vessel. It is acknowledged that occlusion of the great saphena is by no means a novel plan of treatment in cases of varicosity of the lower extremity. It was practised by Paulus Ægineta, and advocated by Ambroise Paré, and at the end of the last century Sir Everard Home performed this operation in twelve cases with very unfavorable results.

Classification of Headaches.—In the *University Medical Magazine*, Dr. Dercum gives the following classification of headaches: I. Organic headaches. II. Non-organic or functional headaches; *A*, headache, with sympathetic nerve involvement—*migraine*; *B*, headaches from purely functional disturbance of nutrition; *a*, headache from anæmia; *b*, headache from hyperæmia; *C*, headaches from disturbances of nutrition from diathetic and toxic causes; *a*, diathetic headaches, lithæmic, rheumatic, diabetic, uræmic; *b*, toxic headaches, malarial, alcoholic, lead, tea and coffee headaches; *D*, headaches of reflex origin, eye headaches, nasal headaches, gastric headaches, cardiac and pulmonic headaches, uterine and ovarian headaches, bowel headaches; *E*, hysterical headaches; *F*, neurasthenic headaches; *G*, headaches associated with the various febrile disorders.

The Action of Prussic Acid in Pulmonary Tuberculosis.— Dr. Koritschoner reports his investigations on this subject. Introduced by the Italian physicians, Brera, Borda, Brugnatelli, and Rasori, prussic acid was employed at the beginning of the century in almost every disease. The most incredible effects were attributed to its healing action; even tubercular cavities were healed by its administration. Rapidly, however, its pan-therapeutic virtues shrank, until now its preparations are used for stomachic cramps and palpitation, and occasionally as a specific against tuberculosis of the lung. Koritschoner resolved to try its efficiency in pulmonary tuberculosis, giving inhalations of the acid in vapor form, made by the action of potassium cyanide and dilute sulphuric acid. Thirty patients with incipient pulmonary phthisis were placed in a chamber two hours every morning and afternoon for six weeks; into this room the fumes were driven, no other treatment being added. The conclusions reached were as follows: Chronic prussic acid poisoning was produced in seven patients; diminution of cough and liquefaction of sputa occurred in all; reduction of pulse and respiration rate occurred in every case; doubtful action on body weight; night-sweats and fever were observed; while there was absolutely no effect on the tubercular process in any way, which increased regularly and steadily throughout the treatment. Realizing the dangers of the treatment, Koritschoner wisely concludes that the results were too small to justify its use in such cases. He believes its reputation is due in phthisical conditions to its sedative action on the cough.—*Wiener Klinische Wochenschrift.*

Gangrene of a Tendon.—Dr. E. Corminas reports, in the *Revista de Ciencias Médicas* de Barcelona for April 10, 1891, a curious case of gangrene of a single tendon without participation of the surrounding tissues. The patient had caught the middle finger of his left hand in a door in such a way that the last phalanx was broken and the soft parts much lacerated. The broken end of the phalanx was removed, the edges of the wound trimmed and drawn together, and an antiseptic dressing applied. For a few days everything went well, but soon the finger began to swell and the swelling extended to the hand. On making an incision a large amount of pus was evacuated, but the swelling in the finger was not reduced. It was thought that possibly a portion of the bone was necrosed, but upon making an incision along the palmar surface of the finger at the level of the first phalanx, a gangrenous odor was perceived, and examination showed a necrosis of the superficial flexor tendon. In the course of four or five days the tendon sloughed away in pieces aggregating in length over an inch, showing that the gangrene had extended well into the palm of the hand. After this separation had occurred the swelling diminished and the wound healed without further accident.

Treatment of Soft Chancre by Grattage.—Dr. N. S. Sheshmintseff reports several cases, in *Russkaya Meditsina*, of March 24, 1891, of soft chancre in which good results were observed to follow scraping out the ulcer and the subsequent application of a powder containing tannic and boric acids, or of a solution of nitrate of silver, 10 grains to the ounce. He believes, as a result of these experiences, that grattage of soft chancres, local anæsthesia having been previously effected, gives better results, as regards the rapidity of the cure, than any other method hitherto employed. When this is done early enough it is almost certain, he holds, to prevent the formation of a bubo.

Paranoia Recurrens.—At the recent meeting of the Society of Russian Physicians in Moscow, Dr. B. S. Greidenberg reported seven cases of recurrent mania which he had observed in his service in the section for mental diseases of the Simferopol Charitable Institute within the last three or four years. The patients, upon their reception into the wards, presented all the typical symptoms of acute insanity, for the most part of maniacal character, and these symptoms continued for a few days or perhaps a week. Then very suddenly, much more rapidly than is usual in such cases, the patient's condition began to improve, and at the end of one or two, or at most three, days it had changed so much for the better that they were regarded as almost, if not entirely, well. Two of them, indeed, who lived near the city, were discharged from the institution as convalescent. At the end of from a few days to a week all these patients who had been looked upon as cured or convalescent began to show signs of their former malady, and in a very short space of time presented all the symptoms of acute mania. After another interval these symptoms began to abate and convalescence was again established, to be followed after the usual period by a return of the mental trouble. Each returning paroxysm was, however, a little less pronounced and of shorter duration than the one that had preceded it. The number of relapses varied in the different cases from two to five. The author emphasizes his belief that these intervals of apparent health were not the ordinary periods of temporary relief to the intensity of the symptoms often seen in the course of acute mania, but were actual remissions, during which there were no signs present of mental disease. Four of the patients were men, and three women. One only was over thirty years of age, the rest were about twenty-five years of age. All recovered perfectly, and several, from whom reports have been received from time to time, have remained well. The author regards this as a hitherto undescribed form of insanity, and gives to it the name of paranoia recurrens. In everyone of the cases observed by him the apparent cause was a violent mental shock. No hereditary predisposition existed in any case.—*Vratch*, March 14, 1891.

Camphoric Acid and Tellurate of Sodium as Antidrotics.—A French author speaks very highly of the use of these drugs in the treatment of profuse sweating from whatever cause. Employed in the nocturnal sweating of

phthisis, their action is prompt in arresting the secretions of the skin, in lessening very materially the purulent expectoration, and in improving the general well-being of the patient. The amount of camphoric acid to be given daily is set down as about thirty grains, and that of the sodium tellurate as rather less than a grain. The ingestion of the sodium salt imparts an alliaceous odor to the breath. No disagreeable results have been found to follow the use of these remedies. Schultze also reports very favorably on the use of camphoric acid in the sweating of phthisis. He advocates the administration of thirty grains every evening at bedtime. According to this author, the antidrotic effect of this drug is far superior to that of atropine, while it produces very much less constitutional disturbance. The effect continues from six to eight hours. Schultze also recommends the combination of fifteen grains of camphoric acid with the usual dose of antipyrine, to counteract the diaphoretic action of the latter drug.—*New York Medical Journal.*

The Scarlet-Fever Tongue.—The method followed by Dr. Newman was to sketch the tongue as soon as the diagnosis of scarlet fever was made, and after two or three days to compare its condition with the sketch already made. This was done in forty-eight cases, the chief symptoms of the disease being noted at the same time. The mucous membrane of the tongue passed through three stages: 1, Swelling and cloudiness of the epithelium; 2, desquamation; 3, regeneration of the lost epithelium. The first thing noted in the scarlet-fever tongue is a swelling of the entire mucous membrane, giving rise to longitudinal folds and channels, easily distinguished from the folds noted in bulbar paralysis by the consistency of the tongue. The cloudiness of the epithelium gives rise to the changed color of the tongue; it appears grayish-white, white, or yellowish-white—that is, the tongue is coated. The back of the tongue is chiefly affected, the sides and tip being red. The desquamation does not take place as uniformly over the tongue as the other processes. It commences on the papillæ fungiformes. These latter appear as submiliary or miliary round, dusky-red dots, surrounded by a white area. Thus the tongue gets its strawberry appearance. In the third stage the sides of the tongue, and more particularly its tip, retain their red appearance and strawberry aspect longer than other parts of the tongue. The new epithelial layer may be so thick that the tongue appears coated anew. The swelling gradually goes away. The above is the usual course, but there may be departures from it. In two cases the dulling of the epithelium was absent, and the desquamation excessive, so that the longitudinal muscle bundles were seen. In another case, the epithelium was only detached in part, and a new layer developed quickly, so that the tongue appeared coated throughout. It resembled a dyspeptic tongue. The author says that the fungiform papillæ appeared round and erect; whereas in the dyspeptic tongue they are elongated, and slope toward the tip of the tongue. Generally speaking, the digestive troubles cause the tongue to be coated before the scarlet-fever process has had time to affect it. If scarlet fever be combined with a septic condition, the latter determines the condition of the tongue. As the new infection appears early or late, so is the scarlet-fever process interrupted. Generally speaking, the tongue, after losing its epithelium, develops a strawberry appearance, and then becomes dry. Bleeding cracks may be seen, which can lead to deep ulceration, or true diphtheritic membrane may appear. Out of the 48 cases the tongue was typical in 38. In 4 cases, one or two of the stages were only very slightly developed; and in 6, the typical scarlet-fever tongue was altogether absent. Of these 6, there was severe gastric disturbance in 2; another case was in a chlorotic girl; in the fourth case there were symptoms of septicæmia, and death on the fourth day; and in the fifth and sixth cases the tongue was quite unaltered. Thus it would certainly appear that the scarlet-fever tongue is a tolerably frequent occurrence in the disease, and that when absent, complication or previous illness has altered the tongue in other ways. The tongue recovers its normal state with the cessation of the fever. In the majority of cases the tongue had lost its epithelium, and had become strawberry in three to five days. There is no proportionate relation between the intensity of the scarlet-fever poison as it affects the skin and tongue. Both processes are probably brought about in the same way, as their tolerably equal occurrence and their appearance much about the same time would suggest; and again, certain departures from the ordinary have shown a peculiar resemblance. Thus in one case with a puerpuric rash, the same was noted on the tongue; and in another, where syphilis was present as well, pustules were seen on the tongue as well as on the skin. Thus this condition of tongue, though not always present, is observed in many cases. It is, however, of less value than it might be, as it does not appear before the fourth day or so, and it may certainly be present in other illnesses.—*Deutsches Archiv für Klinische Medicin.*

Fetid Milk in Human Mammary Glands.—Dr. Jorissenne had under his care in 1874 a patient of slightly tuberculous aspect, though now, in 1891, she is in good health. On October 5, 1874, she was delivered by forceps. She suckled her child freely till December 7th, when she was absent from it for seven hours and a half. This space of time included a drive one hour long, five hours and a half walking, and one hour's rest for refreshment. Immediately on her return home she gave her child the breast. The milk was horribly fetid—like rotten eggs. It made her feel ill, and her relatives could not stay in the same room with her. Yet the infant sucked with avidity; however, it was violently sick. Next day the milk was sweet, and the child and also the mother quite well. The breasts showed no sign of hardness, engorgement, etc. The nipples were healthy. The patient told Dr. Jorissenne that on several previous occasions she had noticed that when she delayed giving the child the breast at the usual times the milk became fetid. Dr. Jorissenne had no further opportunity of observing this putrefaction of milk, as it did not recur. The patient was red-haired; but he has carefully examined the milk of many red-haired women since 1874, and failed to find that it showed any special tendency to putrefy or even turn sour, in the open air or in a close room, more quickly than milk from a black- or fair-haired woman. The avidity with which the infant imbibed the putrid milk was remarkable; its stomach was more sensitive than its nose and tongue. Evidence as to the acuteness of taste in the infant is imperfect. During the first few days of extra uterine life the sense seems undeveloped. The child will take solutions of raw salines without sirup, though a few weeks later it will reject the same compounds nicely flavored. The sense of sweetness is early developed. At the end of a few weeks an infant likes sugar, and dislikes cow's milk unless sweetened artificially. Children of six months, or older, will lick ill-tasting colors off their toys. In Dr. Jorissenne's case, the child liked a milk that smelt intensely fetid and must have tasted nasty, according to an adult's idea of taste.—*Archives de Tocologie.*

Preservation of Hydrogen Peroxide.—For this purpose Kingzett recommends the addition of a small amount of ether. Experiments conducted by the author show that pure hydrogen peroxide lost, in twenty-eight days, ten per cent.; in ninety eight days, 27.4 per cent.; in two hundred days, thirty-nine per cent.; and in four hundred and ninety days, 89.2 per cent. The addition of sulphuric acid reduced these figures to 9, 23, 27½, and 68.3, respectively. Alcohol reduced them to 1, 7, 4, 7.4, and 22.8, respectively, while ether still further reduced them, showing a loss of the peroxide in the times mentioned of 0, 1.3, 2.4, and 15.9, respectively.

MEDICAL RECORD:

SOME FACTS ABOUT THE SEXUAL FUNCTION.

A REVIEWER of Gross's "Treatise on Impotence and Sterility," in the *American Journal of the Medical Sciences*, makes some straightforward and healthful statements regarding the male sexual function, which deserve the attention of all medical men. He says, speaking of the duties which fall to a writer on such a subject as that treated of by Dr. Gross:

"He should set in evidence the incontrovertible fact that the generative apparatus of the male, after half a century of complete disuse, may be capable of procreation; as also the equally established fact that it may accomplish the same end after a similar lapse of time, in the face of the most persistent and frightful abuse. The wonderfully planned conservation of its power, under the jealous protectorate of the recuperative energy of the body, in both health and disease, in precocious development and tardy decline, should be well understood by him who resorts to a therapeutic measure or a surgical mutilation. With this it should be demonstrated clearly that the procreative is far from holding the pre-eminent place among the powers of the body, being often preserved in the fullest measure by the tuberculous, the syphilitic, and the idiotic; that it is often most successfully active in those periods of human life when the best powers of a man are actually immature; and that it may be wholly wanting, or but very feebly developed, in individuals who physically represent the grandest and noblest types of the sex. He should be able to prove rigorously that the words 'potent' and 'impotent,' in the sense of their common usage, have no meaning whatever for the expert, and express chiefly the erroneous concepts of those who employ them, the majority of healthy men being both potent and impotent in this false sense; and, given a fixed moment and certain conditions, the average man will be 'potent' or 'impotent,' according as a thousand factors may operate in the one direction or the other. He should show that the human like the other animal brutes (as, for example, in the type of the North American savage), may, indeed, at all times be competent to effect a rape at will, but that the 'civilized' man, even when governed by immoderate lust, and possessed of unusual vigor, is often 'impotent' in conditions of health. He should be able to demonstrate that there is a prostatic no less than a uterine 'flood and ebb,' in each month, of sexual congestion and its reverse, and point out the fact that as women are distinguished from the females of all other animals (in generations of transmitted inheritance), by a menstruation which may be described as the price of virginity and chastity, so the 'spermatorrhœa' of the male may be a condition of his clean living; and that even when his losses at night occur 'without erections and dreams,' he is in no danger of touching that 'pathological' state described by our author (without correction) in the revised edition before us."

The reviewer, presumably Dr. Hyde, of Chicago, in the above observations, affirms that man may be continent for years without becoming impotent; that the sexual function in civilized man is not the dominant one, is not necessary to the highest type of manhood even, and is not normally increased in the higher processes of evolution; finally, that man "menstruates" in a certain sense as well as woman, this menstruation being the price of his chastity.

The author is particularly severe in his criticism of Dr. Gross's view, that masturbation and so-called spermatorrhœa are frequent causes of stricture and impotence.

DENTISTRY AND SYPHILIS.

THE labors of modern syphilographers have shown that syphilis is relatively often communicated by other means than sexual intercourse. The disease cannot be considered a purely venereal one. Among the methods of innocently transmitting syphilis, that of the practice of dentistry is one to which several writers have called attention. Dr. L. Duncan Bulkley, however, has lately collected with much care all the literature on the subject, and presented it in a very forcible way at a meeting of the New York Odontological Society.

The poison of syphilis, he says, may be received from four different sources, viz.: 1, The initial sore; 2, mucous patches; 3, the syphilitic ulcerations; 4, the blood.

In dental operations it is practically the mucous patch which is the chief source of danger. This secretes a viscid and intensely contagious substance which may adhere to the instruments or the person of the operator. From the infecting person danger arises first to the patients, and second to the dentist himself. Instances are given illustrating the infection of both classes by the syphilitic poison. Fifteen cases of infection of patients by dental operations are cited, and five cases of infection of the dentist. These numbers are not large, and the mode of infection is not established to a certainty in every case. Still enough evidence is furnished to show the reality of the danger, and no doubt many unnoticed or unrecorded cases have occurred.

The infection rarely occurs by direct transmission, although instances of this kind (by tooth transplantation) are on record; more often the disease is transmitted indirectly by means of instruments. Dr. Bulkley says: "The agents and objects which may become the conveyors of the poison are as numerous as the implements and articles which may come in contact with the mouth in dental manipulations. For convenience these may perhaps be grouped in three or four classes, as follows: 1, Instruments proper; 2, napkins; 3, rubber dams, wedges,

dental floss, etc.; and, 4, plaster, rubber, etc., used in connection with the making of artificial teeth and sets."

As a means of prevention it is recommended that the instruments be boiled or dipped in strong solutions (ninety-five per cent. of carbolic acid. "Forewarned is forearmed," and the dentist who understands the possibility of syphilitic infection in his work can easily guard himself against it.

CAN WE COMPLAIN OF SYMPTOMS?

An esteemed correspondent from Providence, R. I., writes us:

"I was recently called upon to testify in a seduction case, and my testimony was to prove the date of menstruation prior to pregnancy. A wrangle occurred between the opposing lawyers as to the admissibility of my testimony, and the judge decided that I could testify only concerning pain or suffering in the patient. I said that she was not in pain and was not suffering, but complained of certain symptoms, and was at once taken to task by the judge, who said that a patient could not complain of symptoms but of facts which were to a professional mind symptoms. It seemed to me that if a patient complained of nausea, of dizziness, and mental worry, she complained of symptoms. Am I correct in the use of the word?"

Our correspondent was right and the judge was wrong, as judges sometimes are.

The term "symptom," in its technical and medical sense, means "a change in the body or its functions, indicating disease" (Webster). Cough is a symptom indicating, perhaps, the disease phthisis. It is both a symptom and a fact. The patient complains of the cough, not of the phthisis or the bacilli which cause it.

The learned judge probably had in mind the other definition of symptom, viz., that of a sign or token. But medical usage identifies the sign with the thing or fact. A person suffers from fever, which is, in many cases, both the symptom and the only fact we know regarding a morbid change.

The Rhode Island judge should correct his views.

CHEAP DOCTORS.

We not infrequently have complaints of cheap medical service of doctors who take a fee of twenty-five cents, or of club doctors who treat hundreds of people annually for the merest pittance. A correspondent recently sends us an illustration of a somewhat new departure in cheap doctoring:

"A day or two ago two insurance agents came to my office and requested me to apply for the responsible (?) position of medical examiner for their company, the compensation being the munificent reward of twenty-five cents a head, and to go to the applicants' houses to examine them at that. I need not say that I politely bowed them out of the office.

"Next day I happened to meet the agent of another company, who had offered me a similar position nearly two years ago at a remuneration of fifty cents per capitem, which of course I respectfully declined. This agent told me he had since then been waiting for some impecunious doctor, and at last his patience was rewarded by finding a new-fledged graduate who is willing to accept the position at the rate of twenty-five cents a head. How are the mighty fallen! Physicians found eager to degrade their profession by giving their services for such a paltry stipend! What is the profession coming to? Why, a poor cobbler can earn as much in a few minutes by patching a pair of old shoes. We must, at this rate, soon exchange the doctor's office for the cobbler's shop."

We read accounts like the above with the feeling that, unfortunate as such things are, they cannot soon be helped. Professional pride disappears very soon in the presence of penury and hunger. There are too many doctors in the country for all of them to get large, or even just, fees; and there are always people ready to take advantage of this fact.

The community ought to learn, however, that cheap doctoring is not safe, and in the end does not pay. It is perfectly impossible for a man who has made himself a thoroughly good physician, and who is conscientious in his work, to live upon these small fees. Those who take them are, in nine out of ten cases, incompetent and untrustworthy, or careless in their work. We should like very much to know what life insurances pay their examining physicians twenty-five cents a head. A publication of their names would kill them among intelligent people within twelve months.

HYSTERIA AND HOSPITAL INTERNES.

The daily papers give an account of a poor woman who committed suicide by drinking a quantity of belladonna liniment. It is stated that the ambulance surgeon mistook the case at first for hysteria; a diagnosis of opium poisoning was then made, and finally one of belladonna poisoning. We cannot vouch for the accuracy of these details, but they are in perfect harmony with a very common and very reprehensible practice which prevails among the young men on the house staff of our hospitals. This practice consists in labelling as "hysteria" a large number of cases that exhibit a little too much moral perversity or emotional excitement. Cases of serious mental disease, of apoplexy, poisoning, and other serious conditions have been diagnosticated as hysteria and treated with the disciplinary severity which it is thought that hysteria in hospitals should receive. A good deal of injustice and neglect sometimes result from this particular hospital habit. It would be well if the house physicians and surgeons were impressed with the fact that hysteria is a real disease, of somewhat rare occurrence, and not particularly easy to recognize. It is not identical with emotional excitement or belladonna poisoning.

THE QUEEN AND THE PRESIDENT.

The Queen of England has gone to Grasse—we make the statement with all respect and spell it with an "e." Her stay there has called forth from the *Lancet* the following gentle and affectionate tribute:

"Her Majesty's stay at Grasse is now drawing to a close, and if certain rumors which reach us from a source on which we have good grounds to place reliance are true, the country will have additional cause to rejoice that Her Majesty returns to England in excellent health. We learn that there have also been a comparatively large

number of cases of such illness as is generally traceable to insanitary surroundings. Moreover, we understand that small-pox has been prevalent about Grasse, and was so at the time of the Queen's arrival there. Doubtless Her Majesty's advisers take measures of precaution when she visits foreign places, but we would point out that where a life of paramount importance to our country is concerned it is absolutely imperative that the most eminent experts in sanitary science should be called in to testify to the hygienic condition of any town or locality proposed to be made the temporary abiding place of our sovereign."

President Harrison has been to California. He has subjected his life to the dangers of an enormously long railroad journey; he has just escaped being blown to pieces by a prematurely demonstrative cannon; he has journeyed over alkali plains, among barbarous Indians and exuberant cowboys, and has experienced the dangers of unboiled water, unsettled weather, and unusual climates, but he is coming back safe and well, and we propose to offer our cordial and unpartisan congratulations upon the event. Our readers are doubtless somewhat divided as to whether Mr. Harrison ought to have been made President; but as he holds this high office, we do not doubt that every one wishes him the enjoyment of good digestion and sound physical health. We cannot express toward the President the same grandmotherly tenderness which our esteemed contemporary, the *Lancet*, seems to feel toward the Queen, but in the essentials of cordiality we need not be behind it.

THE "SWEATING SYSTEM" IN MEDICAL PRACTICE.

We hear a great deal about the "sweating system" as applied to the so-called laboring classes, and of the iniquity of compelling people to work for nine or ten hours a day. But it occurs to us that this same system is not confined to day laborers, artisans, and mechanics. Medical practitioners by contract, those who do work by the year for clubs and friendly societies, are most luminous examples of how the "sweating system" can be applied to men of education and professional skill. Some of the societies pay $1 a year per family, and many pay so small a sum that each professional visit costs but a few cents. Yet the members of these societies are the very persons who cry out against ten-hour days and unjust wages.

We do not advise, however, that medical men indulge in strikes or organized resistance. Such measures offer but brief and inadequate respite from the trouble, and do not in any way alter the inevitable working of economic laws. It is better to teach people the injustice they do and the harm it works upon themselves, and also to teach physicians that they had better leave a profession which offers so inadequate recompense. Meanwhile it is but right to remind the unfortunate "sweated" classes who form the friendly societies that they should do as they would be done by. Such societies had better be abandoned, so far as medical service is concerned, if they work in so pitifully unjust and inadequate a way.

The subject brings to our mind some recent statistics regarding the rewards of medical practice in Great Britain prepared by a medical man and published in the *Quarterly Review*. He estimates the average medical income at about £200 ($1,000), which is rather a small sum surely for the work done and responsibilities assumed.

News of the Week.

The American Medical Association.—The final session of the Association was held on Friday morning. There was a comparatively small attendance, a large number of the delegates having already gone home. The meeting was opened by prayer by the Rev. Dr. John H. Elliott, of the Ascension Episcopal Church of Washington. Dr. Wood read the report of the Committee on the Jenner Centennial Celebration. A number of inquiries had been sent out to men in each State, and to these some twenty replies had been received. There was a practically unanimous sentiment in favor of a celebration of the discovery of vaccination, "the greatest boon that has ever been conferred upon mankind," and some even suggested that three days instead of one be devoted to this celebration. The committee simply recommended that the celebration be held, but thought it best to leave the task of elaborating a definite plan to a standing committee on the centennial, to which also shall be referred all the details of the proposed celebration. The centennial will occur on May 14, 1896. The report was accepted and the committee continued, and a resolution was adopted to hold the celebration, and so to time the meeting in that year as to include May 14th, which day should be given up wholly to the appropriate exercises. Quite a number of the members of the Pharmaceutical Association, which has just closed its deliberations, was present, and Mr. Taylor and Professor Remington of that association were invited to seats upon the platform. Professor Remington read a resolution from the Pharmaceutical Association thanking the Medical Association for organizing a section of materia medica and pharmacy. The committee on the president's address made a report in which it was advised to adopt several of the suggestions there made. The consideration of the proposed changes was, however, laid over to the next annual meeting. Dr. Reed, of Ohio, offered a resolution looking to the incorporation of the Association, which up to the present time has had no legal existence, and after considerable discussion the matter was referred to a committee, which was instructed to report at the next meeting in 1892. The names of the newly elected officers of sections were then read. Owing to the absence of Dr. W. L. Schenck, of Topeka, Kan., the address on State medicine was read by title. On motion it was determined that Congress be memorialized to pass a law for the District of Columbia recognizing the secret nature of the confidences between the physician and his patient. This was in accordance with the suggestion offered by Mr. Ross in his address of welcome on the first day of the meeting. The announcement having been made that certain members wanted to be made delegates to foreign societies, it was moved that they be empowered to act as delegates to all foreign societies except the British Medical Association, which, it was stated, had treated Americans very shabbily. This was opposed by Dr. Davis,

who said that the British Association had always treated the delegates well, the trouble last summer having been solely because the meeting was held in the home of a man who disliked Americans. It was then decided that the president and secretary could give credentials to any society that they thought proper. The new president, Dr. Marcy, of Boston, Mass., was introduced by Dr. Briggs and made a few remarks appropriate to the occasion. After the usual vote of thanks to the committees, physicians, and ladies of Washington, hotels, railroad companies, etc., the Association adjourned to meet in Detroit on the first Tuesday in June, 1892.

The American Medical Temperance Association was organized during the meeting in Washington last week. The new society is modelled after the British association of a similar name. The following officers were elected to serve for the coming year: *President*, Dr. N. S. Davis, of Chicago; *First Vice-President*, Dr. R. Quinby, of New Jersey; *Secretary*, Dr. T. B. Crothers, of Hartford; *Treasurer*, Dr. George W. Webster, of Chicago.

The Continental American Medical Congress.—The committee appointed to consider the question of a Pan-American Medical Congress met in Washington on Thursday last and elected Dr. Reed, of Ohio, *Chairman;* Dr. Carhart, of Texas, *Secretary*, and Dr. Love, of Missouri, *Treasurer*. The officers were appointed a committee to prepare the by-laws and a constitution and to report at an adjourned meeting at St. Louis, October 14th.

The American Academy of Medicine.—The sixteenth annual meeting of this society was held in Washington on Saturday, May 2d, and Monday, May 4th. About thirty of the fellows were present at the opening session. Dr. Charles McIntire read a paper on "The American Practitioner Abroad," after which the reports of various committees were presented. Thirty-six new members were then elected. At the second session Dr. Steiner read a paper entitled "Will the Shortening of the College Curriculum Conduce to Better Preparation for the Study of Medicine?" The speaker did not believe that any good would result from such a course. Dr. McIntire presented another communication entitled, "An Attempt to Determine the Ideal Preparatory Course of Studies for the Learned Professions," and Dr. D. S. Jordan opened a discussion on "The General Education of the Physician." He believed that the colleges should begin the medical training of the future physician by teaching him the elements of anatomy, chemistry, microscopy, botany, etc. The president, Dr. Parvin, of Philadelphia, then read his annual address. The election of officers resulted in the choice of—*President*, Dr. Phineas S. Conner, of Cincinnati, Ohio; *Vice-Presidents*, Drs. R. Lowry Sibbett, of Carlisle, Pa.; George J. Fisher, of Sing Sing, N. Y.; Henry M. Lyman, of Chicago, Ill., and Louis S. McMurtry, of Louisville, Ky.; *Secretary*, Dr. Charles McIntire, of Easton, Pa.; *Assistant Secretary*, Dr. Edgar M. Green, of Easton, Pa., and *Treasurer*, Dr. J. Chester Morris, of Philadelphia.

The following resolutions were adopted:

Whereas, Like the American Medical College Association, it is the purpose of the American Academy of Medicine to promote a suitable and thorough education in all persons who choose the practice of the healing art as their life work; therefore we wish to congratulate the members of the Association on the success which has already resulted from their efforts, and to support them in their undertakings by the following statements:

Be it resolved, That medical colleges should require a preliminary examination of students in the branches which constitute a high-school curriculum, including one year's study of the Latin language, unless said matriculates hold diplomas from literary colleges, universities, or State normal schools.

Resolved, That in our opinion the course of study in all our medical colleges should be graded and extend through not less than three years of eight months each; that the instruction should not only include practical anatomy and abundant opportunities for clinical study, but a thorough training in chemistry, histology, and pathology.

Resolved, That it is the sense of this Academy that there should be in each State a Board of Medical Examiners to promote the foregoing conditions in physicians, also to determine whether practitioners in medicine and surgery, as such, are fit to receive the implicit confidence of the public to which their services are offered.

The Academy then adjourned to meet next year, but without designating the time or place.

Long Island College Hospital, Brooklyn, N. Y.—The regular course of lectures will hereafter be six months in duration. Three courses of lectures will hereafter be required for graduation. Joshua M. Van Cott, Jr., M.D., has been appointed Professor of Histology and Pathological Anatomy, vice Frank Ferguson, M.D., who has resigned.

Mount Sinai Hospital Dispensary.—Dr. W. M. Leszynsky has resigned from the Mount Sinai Hospital Dispensary.

The Society of the Alumni of Bellevue Hospital held its second reunion and dinner on May 13th, at the Hotel Brunswick. Dr. Charles Phelps, President of the Society, presided. Toasts were responded to by Dr. D. B. St. John Roosa, President of the Post-Graduate Medical College; Dr. Starling Loving, of Columbus, O., of the staff of 1849–50; Dr. D. Bryson Delavan, J. C. Alexander, and others. The dinner was largely attended, there being about one hundred and fifty present. Many of the older Alumni from distant places were present, and the occasion was a highly enjoyable and successful one.

The Post-Graduate Medical School held its sixth annual dinner at the Hotel Brunswick, on May 12th. Speeches were made by the President, Dr. St. John Roosa; the Secretary, Dr. C. C. Rice, Mr. F. I. Taylor, Rev. Arthur Brooks, Dr. George F. Shrady, Mr. Garden, and Mr. F. Hopkinson Smith. The school, it was stated, had had an unusually prosperous year. Nearly four hundred and fifty students had been in attendance. The school had been obliged to enlarge its quarters still further, and had purchased two more adjacent buildings. The sum of $5,000 had been given to assist in paying for these, and more money was promised. The annual banquet was a kind of jubilation over the well deserved success of the School.

Odd Names.—Our learned confrère, Dr. George Jackson Fisher, has made a study of the curious names of historic medical men (*New England Medical Monthly*). The list given shows that many estimable gentlemen must have suffered distress of mind at some periods of their lives, on account of their too suggestive and cacophonious names. We all know of Dr. Physic, Dr. Bum, and Dr. Beef, and many are familiar with Dr. Turnipseed, Dr. Diet, Dr. Frey, Dr. Ham, and Dr. Chew. But Dr. Fisher gives us many other names which arouse our sympathies toward their unfortunate but eminent possessors.

Sir James Paget has written a letter to *Nature* setting forth his belief that Pasteur has furnished to the world a real "cure" for hydrophobia. It must be admitted that just now Pasteur is ahead of Koch.

Dr. Virchow Denounces Kochism.—The lower house of the Prussian Diet on May 9th voted 165,000 marks for Professor Koch's institute. Professor Virchow opposed the grant and denounced Kochism, claiming that it had proved a failure. He warned the doctors who were using the lymph that they ran a great risk if they persisted in treating their patients with the alleged remedy.

An Extraordinary and Tragic Accident occurred at a wedding near Louisville, Ky., recently. Sixty guests were present. Of these, forty were taken in from four to sixteen hours with violent and persistent vomiting or purging (or both), attended with great prostration in all, and collapse in some cases. Death was the result in five cases, and it is not certain that more will not follow. The cause was probably ptomaïnes in the chicken salad. Careful investigation failed to reveal any metallic poison or any tyrotoxicon in the milk.

A Law Regulating the Practice of Midwives has been enacted in Minnesota.

The Growth of the Professor.—The Kansas Medical College has appointed a professor of railroad surgery, but this is nothing beside the Post-Graduate Medical College, which has professors of the rectum, of intubation, and of electricity.

College Commencements.—Maryland University has graduated a class of eighty-seven; Niagara University, ten; Virginia Medical College, fifteen; Leonard Medical College, six; Arkansas Industrial University, twenty; Louisville National Medical College, four; Western Pennsylvania Medical College, fifty.

Dr. E. T. Reichert succeeds Dr. Dulles in the editorship of the *Medical and Surgical Reporter*, which journal is enlarged to forty pages.

Sexual Precocity.—Texas has always had just occasion to feel proud of its products, but the following, reported by Dr. A. P. Brown, of Fort Worth (*Medical Standard*), will perhaps awaken somewhat contradictory emotions. Dr. Brown writes: "I lately saw a three and one-half year old weighing sixty-eight pounds, ruddy, fat, and jolly, who has hair two and one-half inches long on his pubis and a penis four and one-half inches long, one inch in diameter, and about four and one half inches in circumference. There is no prepuce. It is believed he has a tolerably good idea what a penis is used for outside of urination."

Rush Medical College.—The chair left vacant by Dr. Parkes's death will be divided by Drs. Roswell Park and Senn. Dr. John Parmenter will succeed Dr. Park at the Buffalo Medical College.

Bryonia was formerly used by Stoerck, the Vienna therapeutist from whom Hahnemann borrowed most of his materia medica, in the conditions in which Hahnemann's disciples use it to-day, pneumonia, bronchitis, pleurisy, rheumatism, and phlegmasia. Bryonia, according to Huchard (*Medical Age*), has an elective action on the serous membranes, and, on account of the substitutive hyperæmia which it produces, can be employed with success in the treatment of phlegmasias of the splanchnic and articulary serous membranes, also in rheumatismal or rheumatoidal affections. The drug was used by Hippocrates.—*Medical Standard.*

The World Moves, Including Alabama.—An Alabama medical society has repealed the rule prohibiting consultation with sectarians.

Medicine has the Right of Way.—At Berlin, a corporation ordinance has been adopted which will give to the carriages of physicians the right of way through streets that are crowded. In order that these carriages may be at once distinguished from others like them, the coachmen who drive them will don a white hat. This new headgear has been proposed for the prevention of embarrassing delays of medical men in the principal thoroughfares, and will become a recognized demand for the right of way at all times.

Michigan is the happy possessor of four kinds of legally recognized doctors, viz., the regular, homœopathic, eclectic, and physio-medical. A bill to regulate the practice of medicine has been agreed upon, and this bill provides for a State board of examiners to consist of three members recommended to the Governor by the Michigan State Medical Society; three members recommended by the Michigan State Homœopathic Medical Society; two by the Michigan State Eclectic Medical Society; one by the Physio-Medical Association of Michigan.

Cannibalistic Therapeutics.—Working under the direction of Brown-Séquard, M. D'Arsonval has made a series of experiments with the juices of different animal tissues, such as the muscle, the glands, etc. He makes these juices aseptic by filtration through the Pasteur filter. No conclusions are yet announced.

State Medical Society Meetings in June.—Pennsylvania State Medical Society, Reading, June 2d, 3d, 4th, and 5th; State Medical Society of Wisconsin, Madison, June 3d, 4th, and 5th; Delaware State Medical Society, Rehoboth, June 9th and 10th; Maine Medical Association, Portland, June 9th, 10th, and 11th; Massachusetts Medical Society, Boston, June 9th and 10th; South Dakota State Medical Society, Chamberlain, June 10th, 11th, and 12th; Rhode Island Medical Society, Providence, June 11th and 12th; Michigan State Medical Society, Saginaw, June 11th and 12th; New Hampshire Medical Society (centennial), Concord, June 15th and 16th; Colorado State Medical Society, Denver, June 16th and 17th; Ohio State Medical Society, Put-in Bay, June 17th, 18th, and 19th; Minnesota State Medical Society, Minneapolis, June 18th, 19th, and 20th; Medical Society of New Jersey, Long Branch, June 23d and 24th.

The American Anthropometric Society, founded for purposes of mutual autopsy, has begun its career somewhat ominously. The President, Dr. J. Leidy, died shortly after its organization, and studies upon his brain have already begun. We shall be somewhat curious to learn who aspires for the vacant chair of the eminent deceased.

How to Stop a Cold.—We are pleased to learn that a distinguished rhinologist has at last got a method which will arrest an attack of cold in the head. Whether this method cures *tuto, cito, et jucude*, may be open to some question, but it is at least profoundly scientific. It is as follows: "The nasal mucous membrane is exsanguinated by means of cocaine. Then the lower portion of the turbinated bone is perfectly dried by pledgets of cotton. Then, with some chromic acid fused on a small probe, the superficial portion of this surface is cauterized from one-fourth to one-third of an inch in diameter. This coagulates the mucus and renders the membrane unyielding, so that the blood cannot return when the effect of the cocaine has passed away. The action of the caustic is not beneficial as a destructive agent, but by its influence in controlling the circulation and so stopping the inflammatory process."

Bacilli in Syphilis.—Dr. von Marschalko, who has been working in the pathological laboratory of the Buda-Pesth University at the subject of the bacteriology of syphilis, has devised a method of staining by which bacilli may be found in syphilitic growths of various kinds, such as papules on the skin, the indurated base of a chancre, and condylomata, as well as in the secretion of primary sores, while he has not been able to find them in non-syphilitic growths or in the secretion of soft chancres. Whether they are really inseparably connected with syphilis can of course only be decided by a prolonged series of observations, but there would at least appear to have been a *primâ-facie* case made out for further investigation. The method employed is by double staining, as follows: The object, after having been hardened in alcohol, is immersed for thirty-six hours in an alkaline solution of methyl blue; it is then rinsed well with water, and restained by a concentrated solution of vesuvin in water. The bacilli are stained blue, and can be easily distinguished from the tissues, which are brown.—*Lancet.*

Tuberculin and Climate.—Dr. Detweiler, of Falkenstein, has been for four months using tuberculin in connection with climatic cure, and his conclusions, therefore, are of especial value. He says he has had four months' experience with 128 patients. Of these, four, or 3.1 per cent., were discharged quite cured and free from bacilli; improved, forty-three, or 33.6 per cent.; stationary, fifty-one, or 39.6 per cent.; worse, twenty four, or 19 per cent.; and six died, or 4.7 per cent. These results are very small in comparison with those hitherto obtained at Falkenstein, and even lower than formerly. His statistics were based on fifteen years' experience. His conclusions were: 1. That tuberculin exerts an action in tuberculosis different from that of any remedy hitherto known. 2. The manner of its action (good as well as bad) is not to be estimated beforehand in any individual case. 3. It is uncertain in diagnosis, since indubitable cases of tubercule do not react. 4. The risks involved are not great, but sometimes surprising, and anxious accidents occur. 5. Its curative effect is but small. It might be better if only very small doses were given. He discountenanced its use in moderate and severe cases. 6. The remedy was not a true specific, since it did not render the lung immune or kill the bacilli. 7. At present a final judgment is not possible, and we are still entitled to expect a curative effect in the smallest foci under a careful use of the remedy.

The Medal of the Berlin Medical Congress.—The great memorial medal of the Tenth International Medical Congress of 1890 is now being struck in silver and in bronze. Its diameter is seven centimetres, and its design is the joint work of Professor Virchow and the government architect Jaffé. Its obverse is adorned with a vigorously modelled Æsculapius sitting on a throne erected on a globe repre senting the earth. The inscription is, "Tenth Interna tional Congress, Berlin, 1890." The reverse represents the city of Berlin as seen from the Column of Victory, with the arms of the city adorned with laurel twigs, surrounded by the arms of the nine most largely represented States and the names of the other thirty-one. Above the view of the city is stamped the name of the member of the Congress for whom the particular medal is destined.

Regulating Medicine With a Vengeance.—Senator Searles, of Texas, is a very funny man. He has intro duced into the Legislature a bill, of which the following are some of the provisions:

"*Whereas*, Much complaint exists in regard to undue discrimination upon the part of physicians practising in the State in giving to one person larger doses of medicine than to others; and whereas, further complaint exists that said physicians exact from their patient exorbitant fees; and whereas a remedy for these evils is imperatively demanded, therefore:

"*Section* 1. Be it enacted by the Legislature of the State of Texas that all pills prescribed or administered by any allopathic physician in the State of Texas shall be of the uniform weight of five grains, and shall be administered in the dose of one pill each and every hour for not less than four consecutive hours nor more than eight hours. All doses of liquid medicine shall be in fifteen-drop doses each, one dose every consecutive hour for not less than three nor more than six hours. For homœopathic physicians one dose of pellets of sugar shall equal five grains in weight and shall be administered as prescribed for allopathic physicians, and all liquids shall be administered as follows: When one drop of medicine is diluted in one barrel of water, the dose shall be one wineglassful; if one drop from the first barrel be diluted within another barrel of water the dose shall be one teacupful, etc.

Section 2. The fees of all physicians shall be as follows: For each visit to a patient fifteen cents per pill per mile, and twenty cents per liquid dose per mile for the first three miles, and two-thirds of said several rates for each additional mile in excess of three miles. In cases of parturition the charges shall be five cents per mile and ten cents per hour for one child, five cents per mile and seven cents per hour for twins, and five cents per mile and five cents each for a litter."

We suspect that Mr. Searles was one of a litter.

St. Louis the Place.—The *Weekly Medical Review* thinks that the *Journal of the American Medical Association* should be moved to St. Louis.

Alcohol in Candy.—The Committee on Public Health reported the following bill to the Massachusetts Senate: "No person shall sell to a child under sixteen years any candy or other article enclosing liquid or sirup containing more than one per centum alcohol, unless authorized under the provisions of Chapter 100 of the Public Statutes and the acts in amendment thereof."

Obituary.

JOHN JEFFERSON MILHAU, M.D.,

NEW YORK.

JOHN JEFFERSON MILHAU, Medical Director of the United States Army (retired), and since a practitioner in this city, died May 8, 1891, at his residence, No. 41 Lafayette Place, of exhaustion, superinduced by abdominal and kidney troubles. He was the descendant of an old French family, the male members of which were more or less identified with the military affairs of both this country and France. His ancestors migrated to the West Indies in the eighteenth century, and his grandfather, a wealthy planter of San Domingo, was compelled to fly from that island during the revolution of 1789. He took refuge in Maryland and there became a citizen of the United States. Surgeon Milhau himself was born December 28, 1828, in Southern France, during a visit of his parents there. The family moved to New York in 1830. On September 14, 1850, he received an appointment as acting assistant surgeon in the United States Army, the year of his graduation from the College of Physicians and Surgeons of New York, and was ordered to duty in California, where he remained until 1854, having meanwhile received his full commission as assistant surgeon, April 30, 1851. In 1855 he joined the expedition against the Snake Indians, and later the Yakima expedition to Washington Territory. He fought through the Rogue River Indian campaign of 1856, and was at Fort Leavenworth, Kan., during the border troubles in 1857. He joined the Sixth United States Infantry in the Utah expedition across the continent in 1858. When the War of the Rebellion broke out he was ordered to the Third United States Artillery, and went to the front in 1861. Two months later he was appointed medical inspector of the Army of the Potomac, and in 1862 medical director of the Third Army Corps, his appointment as Surgeon U. S. A. dating April 16, 1862. He was present at the battles of the Wilderness, Seven Pines, Malvern Hill, Yorktown, and the second battle of Bull Run. He was then made medical director of the military hospitals and troops in Maryland. In 1863 he was appointed medical director of the Fifth Army Corps, serving as such from June 17, 1863, to November 20, 1864. Owing to illness, he was retired and ordered to duty at New York in 1864, and achieved quite a reputation as one of the surgeons in charge of the Central Park Hospital. From June, 1867, to May, 1869, he was medical director of the Third Military District and Department of the South. He was made brevet-colonel, March 13, 1865, and brevet brigadier-general, September 28, 1866. He retired from the army in 1876, and in 1878 married Miss Kate L. Manning, of this city, who died several years ago. During the cholera of 1866 he was stationed at Hart's Island, then a military post, where he remained until the cessation of the epidemic. In 1888 he was appointed Commissioner of the State Board of Charities, from which he resigned one year ago. At the time of his death he was secretary of the Emigrant Savings Bank, a companion of the Loyal Legion, N. Y. Commandery; a comrade of George Washington Post, No. 103, G. A. R.; a member of the United Service Club, the County Medical Society, the Academy of Medicine, and the Society for the Relief of Orphans and Widows of Medical Men. One child, a boy, seven years old, and the disceased's widowed mother, are the survivors of his immediate family. Dr. Milhau ranked as one of the best surgeons of the war, was a judicious operator, a keen diagnostician, and an officer of great executive ability. He was singularly approachable, as affable as he was firm, and during the whole term of his military service never lost the confidence of his superiors in rank or the devotion of his subordinates. He always did his whole duty quietly, unostentatiously, and effectively.

PETER V. S. PRUYN, M.D.,

KINDERHOOK, N. Y.

THERE died in the village of Kinderhook, Columbia County, N. Y., on Monday, May 4, 1891, Dr. Peter V. S. Pruyn, a true physician, a public-spirited man, and a Christian gentleman.

Dr. Pruyn was born in Kinderhook, about fifty years ago, received a collegiate education, and graduated in 1863 from the College of Physicians and Surgeons of New York. After spending a time in the hospitals of continental Europe, his father having died soon after his return, he commenced the practice of his profession, which was continued up to his death.

Dr. Pruyn was a man of untiring energy, true and honorable in all the walks of life, always ready to attend the calls of duty as devotedly in the cottage of the poor as in the home of the wealthy; no case was too hopeless to engage his earnest attention, or labor too great to deter him when duty called. He died of a heart trouble brought on by anxiety, care, and overwork. He leaves a widow and two children.

ETHELBERT CARROLL MORGAN, M.D.,

WASHINGTON, D. C.

IN the death of Dr. Ethelbert Carroll Morgan, which occurred last week at his home in Washington, D. C., the profession of this country has lost one of its most brilliant and useful members. In his short career of but thirty-five years he had won, by force of merit, a foremost position among the best known specialists not only of his own country but of his time.

Dr. Morgan was born in Washington, educated at the Georgetown University, at the Medical Department of the University of Pennsylvania, and abroad. In Europe he was a favorite pupil of Morell Mackenzie, Fauvell, and Schroetter, while subsequently he became personally known to most of the leading laryngologists of the day. He was honored with the best professional positions within the gift of his native city, having been the first professor of laryngology in the Medical Department of Georgetown University, and attending or consultant to the best throat and chest clinics in Washington. For ten years the acknowledged authority upon diseases of the upper air-passages in Washington, he was consulted by the most distinguished visitors and residents of the capital, so that few physicians had so wide, varied, and influential a clientèle as he. Certainly none had a greater number of devoted friends. Although one of the youngest Fellows of the American Laryngological Association he was, two years ago, elected its President. His contributions to scientific literature have been numerous and of the highest order. Of aristocratic lineage himself, the standards of his life, private as well as professional, were such as to constitute him an example all too rare. In character gentle, lovable, and pure, yet strong, courageous, and of indomitable will; a finished scholar, a devoted physician, a courtly gentleman; a man the full extent of whose loss cannot be estimated.

Society Reports.

American Medical Association.

FORTY-SECOND ANNUAL MEETING.

Held in Washington, D. C., Tuesday, Wednesday, Thursday, and Friday, May 5, 6, 7, and 8, 1891.

(Continued from page 548.)

SECTION ON PRACTICE OF MEDICINE AND PHYSIOLOGY.

SECOND DAY, WEDNESDAY, MAY 6TH.

Treatment of the First Stage of Pneumonia.—DR. J. W. SMALL, of New York, read the paper, in which he first briefly referred to other methods of treating the first stage of pneumonia, and then described that which he had found successful in cutting short the attack in many cases the past twenty years. The principle of its action consisted in drawing the blood from the seat of congestion to the surface. The feet were first rubbed, then gradually immersed in a mustard bath. Then poultices of flax-seed and mustard were applied, one over the thorax in front, one behind, one over the area of pain. He also gave some aconite and spirits of nitre every half hour, then every hour, finally every two hours. A profuse perspiration was set up, and within fifteen hours the temperature and pulse would be found nearly normal. He often gave a powder composed of equal parts of nitrate of potash and Dover's powder.

DR. F. W. GOODELL, of Vermont, advocated the use of veratrum in every case of pneumonia.

The Therapeutic Value of Mineral Waters. — DR. SMALL also read a paper and recited some cases illustrating the value of certain mineral waters in various chronic affections, particularly diabetes, Bright's, anæmia, chlorosis, etc.

Some of the Remote Effects of Injury to the Brain in Delivery.—DR. F. W. GOODELL, of Bennington, Vt., in a paper with this title, argued that right-handedness was due to injury to the left side of the brain, especially the motor area, during labor. In a considerable majority of cases the left side of the fœtal head, particularly the parietal region, took the advance, and was exposed to the greatest amount of pressure. He expressed the view that the caput succedaneum was due to absence of support at this point, and said that doubtless in many cases there was extravasation into the brain beneath as well as into the integument. In the course of centuries there became established a hereditary tendency to right-handedness.

DR. PUTNAM, of Boston, and others who discussed the paper, opposed the theory. Dr. Putnam was of opinion that children used the right and left hand indifferently, and later copied the custom of using the right hand from their parents and associates. He thought heredity had little to do with it.

DR. GOODELL replied to some criticisms, that heredity determined right-handedness in those born by breech presentation and Cæsarean section.

Recent Contributions to the Knowledge of Diphtheria.—DR. J. LEWIS SMITH, of New York, excluded from consideration in this paper the question of treatment. The great annual mortality from diphtheria justified the amount of literature devoted to it the past few years. It had been well established that true diphtheria was due to the Klebs-Loeffler bacillus or its ptomaïne. But certain other microbes were also capable of producing an inflammation with a pseudo-membranous exudation. The latter, however, unlike the Klebs-Loeffler bacillus, did not cause a certain form of nephritis and nerve paralysis.

Pseudo-membranous diphtheria occurred mostly during the course of some eruptive fevers—scarlet fever and measles. The paralysis and nephritis in true diphtheria were attributed to the ptomaïne of the Klebs-Loeffler bacillus.

Methods of Propagation.—Under this head the author spoke of diphtheria carried to the country by clothing shipped by the fresh-air fund; of spreading the disease by mild "walking cases;" by school rooms from which affected children had not been excluded; by open sewers. It was largely from exposure to walking cases and sewer gas that diphtheria was so prevalent in New York. The paper also contained cases in which diphtheria had been contracted from cats, birds, and other domestic animals. The vitality of the Klebs-Loeffler bacillus and its attachment to the person and articles was remarkable, extending over months and even years. In doubtful cases the microscope should be employed in determining the presence or absence of the Klebs-Loeffler bacillus. Diphtheria was often mistaken for follicular amygdalitis.

A Doubter.—DR. ECCLES, of Brooklyn, thought the author had gone too far in assuming that the presence of the Klebs Loeffler bacillus in a given case proved that it was one of true diphtheria, and its absence that it was one of pseudo-diphtheria. He referred the members to the paper of Dr. Vaughan, who had found true diphtheria produced by other bacteria, the Klebs-Loeffler being absent. In the same paper it had been shown that oil of gaultheria, for example, could be the product of plants of entirely different variety as well as of the wintergreen plant. He thought the same was true of germs, different ones might produce the same poison.

DR. OSLER said, with regard to the diagnostic value of microscopic examination, that very recently Dr. Welsh had been enabled to pronounce two cases as belonging to true diphtheria by finding the Klebs-Loeffler bacillus.

DR. VAUGHAN said he had made microscopic examinations in a number of cases in three epidemics of diphtheria, in the first two epidemics he had no difficulty in finding the Klebs Loeffler bacillus, but in the third, one-half of the cases proving fatal, usually with suppression of urine, he was unable to find this bacillus in any case. Here was a very fatal epidemic, the membrane was like that of true diphtheria, was it proper to call these cases not true diphtheria, but pseudo-diphtheria? If one admitted that the disease was produced by a ptomaïne, it should be remembered that different germs were capable of causing the same chemical poison or ptomaïne.

Cellars and Diphtheria.—DR. C. R. EARLEY, of Pennsylvania, gave a rather remarkable experience with diphtheria occurring where there were damp cellars. Disinfection and ventilation of the cellars caused the limited epidemic to disappear.

Character of the Evidence Respecting Arsenic as a Domestic Poison.—DR. JAMES J. PUTNAM, of Boston, attempted in this paper to show that the assumption that arsenical poisoning might occur from wall papers, etc., was without basis. As in slow poisoning with impure water, and by other means, so in that by arsenic, where there were few cases with marked symptoms there were many in which there was lesser impairment of the health. At Harvard the urine had been found to contain slight amounts of arsenic in a considerable number of people who were not taking arsenic. Then, too, this poison could accumulate in the system gradually in considerable quantity, for the reason that it was slowly excreted. Professor Wood, for instance, had found arsenic in the urine three months after the drug had ceased to be administered. The author said his paper contained reports of some undoubted cases of domestic arsenical poisoning, and expressed the belief that this was the cause of many cases of anemia, certain skin affections, etc.

DR. WOLF, of Philadelphia, said he had not infrequently found arsenic in the urine of persons not taking the drug medicinally, but he did not think it produced poisonous symptoms, for the reason that he had not infrequently administered it in very considerable quantities, even twenty five minims, without poisonous effects.

Drs. Osler, Earley, and Cronyn had seen no instance of presumable domestic arsenical poisoning. It seemed unreasonable to suppose it should happen, when the drug was so frequently administered in large quantity with immunity.

Naphthalin in Typhoid Fever, based on One Hundred Cases.—Dr. L. Wolf, of Philadelphia, read a paper with this title, "No Germicide Administered in Less than a Poisonous Dose Would Kill the Germs in the Intestinal Canal." Might not one be found which in safe doses would remain in the bowel, rendering it unfavorable for the development of the typhoid germs? He thought this was probably the explanation why the naphthalin treatment in one hundred cases had given better results than other methods in the same and other institutions. It was true the mortality had been ten per cent., but excluding the cases practically dying when brought to the hospital, this percentage would be reduced to two per cent. He thought naphthalin would be found more effectual than calomel in the treatment of typhoid fever, but it should not be used to the exclusion of other measures. Probably no remedy would counteract the toxic effect of the bacteria, but benefit would probably follow the cold bath.

Antiseptic Treatment and Liquid Diet in Typhoid Fever.—B. M. Griffith, of Springfield, Ill., had found antiseptic and antipyretic treatment of typhoid fever shorten the attack, make complications less likely, and render the patient more comfortable. The depressing antipyretics like antipyrine and antifebrine were not without danger. He used the salicylates for their antipyretic effect, and phenacetin as an antiseptic. He impressed the need of liquid diet, milk in particular, also alcoholic stimulants. The ice-coil should be avoided because rendering intestinal hemorrhage and lung and cerebral congestion liable.

Dr. Osler had administered naphthalin in a number of cases of typhoid fever, had found it control the diarrhœa, that it did no harm, but he did not think it had shortened the attack. He wished all would remember the words of Nathan Smith, to treat fever cases with plenty of fresh air, cold water, and (not least) not too much medicine.

Too Much Medication.—Dr. Levick, of Philadelphia, Pa., recalled the teachings of Dr. George B. Wood, and expressed strong regret at the great diversity of drugs which had come to be recommended in the treatment of typhoid fever. Watch, if not pray, was most called for. He was convinced that digitalis had many times caused the flagging heart to cease to beat, and other drugs do much if not as great injury.

Dr. John Cronyn, of Buffalo, N. Y., spoke of the benefit of hydrochloric acid, but opposed too much medication.

Dr. Wolf said, in closing the discussion, that quinine acted as an antipyretic when given in large doses in typhoid fever, but it proved otherwise injurious. Whiskey would act as a heart stimulant, it was true, but was seldom called for.

Third Day, Thursday, May 7th.

Epidemic Cerebro-Spinal Meningitis.—Dr. J. S. Nowlin, of Shelbyville, Tenn., read the paper. The name of the disease was misleading with regard to etiology and pathology. It was not, he thought, an inflammation. Death occurring often within five days was sufficient proof of this.

The author gave the history of five cases which he had seen in 1888, three occurring in the same family, two of these and two others ending fatally. He attributed the origin of the disease to drinking water from a spring in the enclosure of which grass and all manner of things had accumulated. The primary impression was upon the nervous system, and was, he believed, due to malarial poisoning. The clinical symptoms and success of treatment by quinine lead to this conclusion. The prodromal nervous symptoms were such as are seen in malarial fevers—headache, pain in the back, epistaxis, herpes. Then one of his cases also had a recurrence. The idea that cerebro-spinal fever was of malarial origin was not new, but its general recognition was necessary if we would successfully combat the disease. The treatment should be the energetic use of quinine, and he recommended its administration hypodermically, say, five grains of the bisulphate, dissolved in warm water, every hour. Quinine should also be employed as a prophylactic.

Dr. Dock said he did not think all cases of cerebro-spinal meningitis could be ascribed to malaria, since the former disease occurred when the severe forms of malaria do not occur. At the same time it was important to remember that malaria may simulate, and frequently does simulate, inflammatory disease of the central nervous system. It is important to recognize this fact, since in the malarial cases a remedy must be used which in the inflammatory cases would be considered dangerous, *i.e.*, quinine. No matter how deep the coma, or how severe the maniacal excitement or convulsions, quinine, in these cases, must be used boldly. Forty or sixty grains must be given in a few hours, and for a sure effect must be given under the skin, and if given early and boldly life will be saved.

As to diagnosis, this can be done with absolute accuracy by the microscopic examination of the blood.

Dr. Nowlin remarked that malaria existed practically everywhere.

The Presence of Albuminuria in Persons Apparently Healthy.—Dr. W. B. Davis, of Cincinnati, reported in this paper further on the case related in his paper read at the last previous annual meeting. The urine continued to show albumin, the man, however, had not been ill in ten years. Diet had no influence on the quantity of albumin present. It was only a short time ago, when albuminuria was supposed to invariably indicate nephritis. This view had of recent years been shown to be grossly erroneous, yet the general practitioner was still unnecessarily alarmed when albumin was found, although all other symptoms of nephritis might be absent.

Granger Stewart believed that albumin was sometimes present in the urine in two-thirds of the population. Another author believed it to be present in small amount in the urine of all persons, and Senator accepted this view.

Dr. Eccles, of Brooklyn, and Dr. Simmons, of California, had also found albuminuria in many persons in apparent health.

Euphorbia Pilulifera in Spasmodic Asthma.—Dr. J. H. Jenkins, of Tecumseh, Mich., sent a paper, read by Dr. Dock, in which the history of several cases of spasmodic asthma treated by this drug was given.

The drug was obtained from Australia, where it had a reputation in bronchial affections. The author administered equal parts of the fluid extract of euphorbia and glycerine, dose about one teaspoonful. It had been of benefit in most of the cases of spasmodic asthma.

Koch's Method for the Cure of Tuberculosis.—Dr. Karl von Ruck, of Asheville, N. C., gave in this paper an account of twenty-six cases of pulmonary and laryngeal tuberculosis treated by injections of tuberculin. His conclusions were that the remedy could be employed and all unpleasant symptoms or danger be avoided. While he believed that he had derived benefit from the method, yet the experience of many men would be required to establish the value of the remedy. For diagnostic purposes, he would use it only to exclude tuberculosis. The heart was more readily influenced by excitement during the treatment. He had not found albumin or casts in the urine.

Tuberculin in the Treatment of Tuberculosis.—Dr. S. P. Kramer, of Cincinnati, also read a paper giving some experience with this remedy. He thought the pendulum was swinging back too far. "That the remedy is a spe-

cific in tubercular disease no one who has seen its action in lupus will doubt." The cure of a single case was sufficient proof of this fact.

Dr. Earley, of Pennsylvania, thought the case of phthisis pulmonalis could be stated in the form of two interrogatories: 1. What are the indications to be met? 2. How to meet them?

Dr. Simmons, of California, thought tuberculin had fallen unjustly into discredit. While he did not think it a cure for all cases, he believed it was the most effectual remedy now at command.

Tuberculin at Johns Hopkins.—Dr. Osler said that on the whole the results at Johns Hopkins Hospital had not been very encouraging. There were about twenty-four cases in all. Five had been benefited. They were chronic, but the lesion in each was strictly limited. The unfavorable symptoms had been in the direction of extension of the disease previously limited, marked hectic, general aggravation of the symptoms.

Dr. Welch said he had made the post-mortem in one case referred to by Dr. Osler, the patient having died during the injections, and a simple croupous pneumonia was found to be the cause of death. In a case of tuberculosis of the knee, it was necessary to make excision during the course of the treatment, and a study of this specimen led him to think it possible that the remedy acted by causing the diseased process to become encapsulated.

Dr. Vaughan said he had made injections of filtered bacterial product in no way connected with tuberculosis (bacteria of water) in healthy persons and two consumptives. In the former it increased the temperature gradually up to between 100° and 101°, in the tubercular cases about the same amount. The latter said they were improved. He had employed tuberculin in eight cases without apparent benefit.

Action of the Turkish Bath in Disease.—Dr. Charles H. Shepard, of Brooklyn, read the paper. The temperature of the body was maintained at the same degree in an atmosphere far below freezing of water, up to and over 300° F. It was done through the action of the skin. The value of diaphoresis was recognized by Eastern countries in various affections. It was of the greatest importance in prophylaxis, as well as in such diseases as nephritis, phthisis, skin affections, etc.

The Turkish bath had not received in this country the attention its importance deserved. Nearly all eminent authors had testified to its usefulness.

Further Studies in Malarial Disease.—Dr. George Dock presented some of the points contained in his paper which bore this title. His observations regarding the plasmodium did not differ from those already published. During the year he had studied the blood in seventy-six cases in which the question of malaria had arisen, in forty-one the diagnosis of malaria being confirmed by the presence of the plasmodium. The others included cases of sepsis, intermittent neuralgias, etc. In all he first attempted to make a diagnosis by a study of the clinical symptoms, which he regarded of much importance in making us better acquainted with the disease. To show the value of microscopic examination of the blood in cases where the diagnosis was doubtful, he cited the case of a locomotive engineer who had been treated by different physicians for supposed malarial dropsy. Dr. Dock failed to find the plasmodium, although quinine had not been taken for some time. Examination of the urine revealed albumin in such quantity as to make a diagnosis of nephritis entirely safe. Under the circumstances large doses of quinine would have done harm. The milder cases of malaria were seen in the spring, the severer ones in the fall. There were certain reasons for supposing that some of the symptoms were due to absorption of a chemical product developed in the system rather than to the germs themselves.

Dr. Osler said it was very difficult to differentiate malarial remittent from typhoid fever, and at Johns Hopkins they always had the blood examined for the plasmodium as soon as doubtful cases were brought in.

Dr. C. R. Earley suggested that it might be well to appoint a committee to report at the next annual meeting whether germs caused the disease or the disease caused the germs!

Dr. Eads, of Washington, was elected chairman, and Dr. French, of Cincinnati, secretary for the ensuing year.

Electricity as a Therapeutic Agent.—Dr. William J. Herdman, of Ann Arbor, took a rather hopeful view, according to this paper, of the therapeutic future of this agent. Its application was either as a stimulant, a sedative for its electrolitic, cataphoric, or caustic effects. It aroused vital action, improved nerve activity, hastened osmosis, excited the secretions, quickened the circulation, aided elimination, allayed pain, made hypodermic medication possible without breaking the skin; it destroyed moles and nævi, removed hair, checked lupus, healed bedsores, dissolved colloid growths and strictures of the rectum, urethra, etc.; it coagulated blood in aneurisms, etc. He thought it entirely practical to draw the current from electric light wires. He had employed the Edison current the past two years without accident. It was perfectly safe.

(To be continued.)

TENNESSEE STATE MEDICAL SOCIETY.

Fifty-Eighth Annual Meeting, held in Nashville, April 14, 15, and 16, 1891.

First Day, Tuesday, April 14th.

The Society met in Watkins Hall, and was called to order by the President, Dr. George A. Baxter, of Chattanooga, at 10.30 A.M. Prayer was offered by Rev. C. D. Elliot, of Nashville.

Abscesses was the title of the first paper, read by Dr. T. J. Happel, of Trenton. He said this field was a profitable one for thought and investigation, especially in the direction of diagnosis. So far as the treatment goes, the Latin expression *ubi pus, ibi incisio*, gives us the therapy of such cases in a few words, so far as their last stages are concerned. The prophylactic treatment is a different matter. Everything that can be done to prevent the formation of pus, to prevent the development of an abscess, must be resorted to, but when pus is present the knife is the instrument for relief. An aspirator can remove the pus itself, but the cause of it, the pyogenetic something, is left behind. A free outlet must be given to the pus, the cavity carefully cleaned, perfect drainage secured, arrangements made for thoroughly flushing the diseased organ with antiseptic fluids, the strength of the patient maintained by a generous diet, and nature aided by an abundance of pure fresh air to repair the broken-down constitution.

Abscess of Spleen.—Dr. Happel reported a case of abscess of the spleen. He said this was a rare trouble, many of our best authorities never having met with a single case. He had in the course of seventeen years' practice found two cases; one due to pressure upon the organ, and the other to chronic malarial poisoning. He also reported a case of abscess of the cornea forming hypopyon, and one of the liver, which came under his observation. In closing he called attention to the peroxide of hydrogen as one of the best, if not the best, of all agents, used to cleanse and restore to a normal state all pyogenic membranes, surfaces, and cavities. As one writer expressed it: "It hunts out pus in all its ramifications as a ferret does a rat."

Ovulation and Menstruation.—Dr. George R. West, of Chattanooga, read a paper with this title. He said that many men held to their individual opinions in respect to this subject, and insisted upon remaining in darkness rather than to be disturbed by the entrance of facts which might bring light. The subject of ovulation and menstruation, their dependence or independence, is one

of those fields where individual opinions and theories run riot, and where the light of facts gained from research and experience is so perverted as to render uncertain the supposed certainty that has previously existed.

After giving a *résumé* of the literature on the subject, Dr. West drew the following conclusions:

1. That the increased familiarity with the pelvic organs, the result of modern surgery, has not materially added to our knowledge of their functions.

2. That though the ovular theory of menstruation has not been overthrown, yet the weight of accumulating evidence seems against it.

3. That the most recent observations point to a common nervous origin for both ovulation and menstruation, and yet an individual independence.

Treatment of Pneumonia.—Dr. Thomas M. Woodson, of Gallatin, contributed a paper on this subject, in which he briefly reviewed the literature on pneumonia to illustrate the opinions of medical teachers and writers. He extolled veratrum viride, and said that it is very useful in the first stage of the disease. Its two alkaloids possess different influences, but between them they fulfil every object that is sought for. Jervine, a powerful vaso-motor depressant, relaxes the walls of the blood-vessels everywhere, at the same time it so quiets the action of the heart by an action over its muscle or ganglia as to reduce its force, thus preventing engorgement of the lung; while veratroidine, by stimulating the inhibitory nerves of the heart also slows its beat, fills the ventricles, and allays excitement. The advantages of veratrum viride are its completeness and rapidity of action; the fact that it preserves in healthy blood-vessels the blood which may be needed in the crisis, if the disease is not aborted; and its safety.

In the first stage of croupous pneumonia the indications, said the speaker, are clear. 1. Control the circulation and diminish the determination of blood to the lungs. 2. Reduce the temperature if high. 3. Allay pain by both physical and physiological rest. 4. Support the vital powers.

The first two indications are met by veratrum viride better and with more certainty than by any other remedy. For the third, to allay pain, we have but one remedy—opium or its salts. The support of the patient, with especial reference to failing heart and respiratory centres, is accomplished by digitalis, strychnine, and alcohol.

More than twenty years ago the speaker expressed the opinion that in inflammatory affections veratrum viride was a sedative of the greatest value, controlling the action of the heart as effectually as blood-letting, without the exhaustion incident to the latter. Arterial excitement is reduced by it, while the vital forces are economized. It is especially adapted in pneumonia in the stage of engorgement, in which it appears to bring about prompt resolution. It may be used in the treatment of children with safety. Its constitutional effects having been secured there is a reduced force and frequency of the circulation, reduction of temperature and respiration, and an amelioration of all the symptoms of the disease. While extolling the virtue of this drug he would not rely on it alone in pneumonia, as opium was unquestionably entitled to a prominent place, being both palliative and curative in its action, allaying pain, cough, and nervous irritation.

Phthisis Pulmonalis, with Especial Reference to Prophylaxis, was the title of a paper contributed by Dr. J. R. Buist, of Nashville. As physicians, impressed with the claims of suffering humanity, we should never relax our efforts as long as consumption, with its multiplied ills, afflicts our race. Nor have we any right, as scientists, to despair of the ultimate triumphs of knowledge and the practical results of scientific research. The acknowledged failure of all the proposed plans for the cure of phthisis, based upon therapeutical agents, should lead us to other lines of effort for its destruction. The impossibility of procuring for the mass of consumptives the benefits of climate and altitude, even if these benefits approximated the value some assign them, should also admonish us to look to the higher plane of preventive medicine in dealing with this disease. Regarding Koch's parataloid as a remedy for consumption Dr. Buist said the high expectations so recently excited by these inoculations do not seem to be verified. Certainly for advanced stages of phthisis, and many other forms of tuberculosis, it is unsuited and positively dangerous; and it is not settled whether any benefit can attend its use in the incipient cases. Preventive medicine is, after all, the acknowledged aim and end of scientific research. Though still in its infancy, it has accomplished wonders for humanity. And it is obvious that its first and highest triumphs are to be won among the class of zymotic and infectious maladies. The power of prevention is incalculably more precious than any therapeutical measures. It is therefore highly incumbent upon us, individually and collectively, to assure ourselves of the modern theory of consumption, and so convinced, we should direct our attention and efforts to a rational prophylaxis of this fatal disease. It may be said that the true difficulty is to get the public to realize its danger from various sources, and, still more, to have wise prophylactic measures adopted. This is in the main true; yet education can perform wonders. The benefits of sanitary reform are now acknowledged and trusted, although fifteen years ago it met with indifference and opposition.

The public were invited to attend the evening session. Addresses were delivered by Hon. William Litterer, Mayor of Nashville; Hon. H. H. Norman, and Judge J. M. Dickinson. Dr. George A. Baxter also delivered at this session the Presidential Address, his subject being "Topics of Import to the Profession and Public." The address was scholarly, very instructive, and was listened to with marked attention.

Wednesday, April 15th—Second Day.

Chronic Endometritis.—Dr. J. S. Cain, of Nashville, read a paper on this subject, in which he said the question as to the localization of the chronic form of endometritis is rendered more prominent than that of the acute form on account of the conflicting opinions entertained by distinguished authors and teachers. None, he believed, questioned the very frequent occurrence of chronic cervical endometritis; but Drs. Emmet, Bennett, and other very distinguished authorities, almost absolutely ignored the existence of chronic corporeal endometritis as a special disease, and consequently, except for the relief of hemorrhages, and to meet temporary emergencies, discountenance all intra-uterine medication, relying entirely upon treatment directed to the uterine os and vault of the vagina. But the great preponderance of medical authority is averse to the opinions entertained by these gentlemen, and with the latter class he was entirely in accord.

Chronic endometritis, and the conditions necessarily allied therewith, are the most common, as well as the most important, diseases with which the gynecologist has to deal. This condition is often a sequel to the acute form of the disease, and grows out of repeated acute attacks. It matters not how or from what source the acute outbreaks originate, whether from catarrhal, specific, traumatic, or internal constitutional causes, they are often, but not always, the starting-point from which not only the endometrium, but the entire uterine and peri-uterine parenchymatous structures become involved. He would here venture the assertion, that while the changes in structure and function of the lining membrane of the uterus often seem to be the most prominent conditions, and those which demand our first and most careful attention, this tissue is probably never chronically diseased without a corresponding involvement of the entire uterine structures.

Treatment.—While the curette is a blind instrument

and capable of doing harm in careless and incompetent hands, yet for the removal of fungoid vegetations and adenoid degenerations from the endometrium it affords the surest, speediest, and safest means as yet devised. Dr. Cain was accustomed to follow the curetting by an application of Churchill's tincture of iodine of diluted carbolic acid, and always preceded the treatment by a careful washing out of the vagina and uterus with a one to two thousand corrosive sublimate solution.

In cases where this treatment is not admissible, or where it has failed to afford relief, his next reliance is on the electro-chemical action of negative galvanism, in removing the vegetations after the method of Apostoli. This is accomplished by introducing an electrode, insulated to near the point, into the uterine cavity, and connecting with the negative pole of the battery, connecting the other pole with a large pad of moistened potter's clay, sponge, or prepared cotton, placed over the abdomen. The time for employment of the galvanism at each treatment should be from ten to fifteen minutes, and the treatment should be repeated about twice a week.

The strength of the current to be employed will depend much upon the acuteness of the particular case, and the susceptibility of the patient to electrical treatment. The chronic cases always require the stronger current. The dosage may be fixed at from ten to three hundred milliampères; the minimum is, in his judgment, too small to accomplish any good results, and yet physicians with much larger experience have had to employ it.

This line of treatment he considers free from many of the objections to others; it is cleanly, free from pain, and exempt from danger. Unlike cauteries and escharotics, it can be limited in its influence and produces no deleterious effects upon the sound tissues, nor does it leave a raw and exposed surface, like the curette, to absorb poisons and septic agencies, and while it removes the vegetations it imparts renewed tone and vitality to the diseased organ.

Retained Placenta in Miscarriage.— Dr. A. J. Swaney, of Gallatin, contributed a paper on the treatment of this condition. He said the dangers from retained placenta in miscarriage were hemorrhage and septicæmia. Those who favor active interference when the delivery of the placenta is prolonged are Tyler Smith, Murray, Simpson, Leishman, Mundé, Grandin, and many others. The reasons given for active interference are the frequency of these dangers in prolonged delivery of the placenta. Simpson directs that if the cervix is dilated or patent to act at once; if it is not dilated he dilates it at once. The woman is then anæsthetized, the uterus depressed as much as possible by the external hand, and with the index finger of the other hand he removes the placenta and membrane. If he cannot sufficiently depress the uterus with the hand, he does not hesitate to forcibly drag it down by a double tenaculum fixed in the cervix. Mundé and Grandin go still further and curette the cavity of the uterus with special instruments made for the loosening of adherent placenta and its removal from the uterus. The authorities who counsel waiting for serious complications before interfering are just as many, and among them are Ramsbotham, Davis, Burns, Fleetwood, Churchill, Grailey Hewitt, and many others. Active intervention does not mean unnecessary interference. Nature is ever to be given a chance, but when we see that her efforts are futile certainly it is but rational to assist her, and this should be done, as directed by Mundé, by placing the woman in the left lateral position and with a dull wire curette removing the placenta, or any part of the secundines that may remain, through a Sims speculum. This is far better and easier than the method advised by Simpson, of dragging or pressing down the uterus and introducing the finger into the uterine cavity. The uterine cavity should then be washed out with hot water, slightly carbolized, every six or eight hours until all fetor has disappeared from the lochial discharge.

Hemorrhage after miscarriage, even when we believe the placenta and secundines have been removed, invariably means retention of a part of the placenta or secundines. Profuse hemorrhage may occur for weeks from this cause, and in such cases we should boldly explore the uterine cavity and remove any offending matter that may be present. In the first twelve weeks of pregnancy the dangers from hemorrhage and septicæmia are not so great, and the expectant plan is more justifiable. After the third month it is criminal negligence to wait and subject a woman to the dangers arising from retained placenta when she can be relieved by an operation, which, if properly done, can do no harm, and spare her the risk of hemorrhage and septic poisoning. In short, the author believed the early removal of the secundines is easy and safe, and forthwith guarantees the woman against the dangers of hemorrhage and sepsis.

Indigo as an Emmenagogue.—Dr. J. L. Jones, of Bells, said his attention was first directed to this drug as an emmenagogue, July, 1887, from an essay published in the *Medical and Surgical Reporter* of Philadelphia, by Dr. S. L. Gount, of Lafayette, Ind. Acting on the suggestions offered by Dr. Gount he had used it in many and various cases. His first case was a young lady, aged twenty, who had not menstruated in five months. He had been treating her for three months with the usual remedies without any effect, so he made up his mind to give indigo a trial, which he did. He ordered indigo ʒ ij., subnitrate of bismuth ʒ ss., well mixed. Of this the patient took one-half teaspoonful in one third of a glass of water, three times daily, for nearly four weeks, when one day he was sent for in great haste. On his arrival he found the patient on the bed, and comfortable. He was then told by the mother that her daughter, while walking in the garden, without pain or warning of any kind, began to flow. The gush was followed by a gentle flow, which lasted only for a short time. In five days she was well, and has not suffered from amenorrhœa since. Dr. Jones has since used indigo in thirteeen cases with but one failure, and this case proved to be pregnant. During the administration of the drug the os uteri becomes soft and patulous, admitting the end of the index finger. There is often a serous discharge from the vagina. The urine becomes brownish-green in color and its odor is offensive. The stools are watery and offensive.

Thursday, April 16th—Third Day.

Diabetes.—Dr. J. A. Witherspoon, of Columbia, read a paper on this subject, confining his remarks principally to diabetes mellitus. He said the term diabetes mellitus is a symptomatic one, being a deviation from health in which the processes of nutrition are seriously deranged, and presenting a group of complex symptoms, the most conspicuous of which are, first, frequent micturition, passing large amounts of pale saccharine urine. Coincident with this is a most insatiable thirst and dryness of the mouth and fauces, which is by far the most annoying symptom, the freest draughts of water giving but little or no satisfaction. The skin becomes dry and harsh, with complete absence of perspiration, and followed by a general pruritus, sometimes impossible to relieve. These were some of the many symptoms of the disease.

The etiology is yet an unsolved problem. Diabetes mellitus is an affection of adult life, but few cases being reported in children, and those always fatal. The only recovery reported, so far as the speaker is aware, was in the case of a girl twelve years of age.

The treatment is conveniently divided into dietetic, medicinal, and hygienic. The dietetic is by far the most important. We must exclude from the bill of fare all food-stuffs containing starch or sugar, for two reasons: 1. The normal action of the liver in its glycogenic function is seriously deranged so that it is incapable of oxidizing the maltose sent to it by the digestion of carbo-hydrates, and these are therefore useless aliments. 2. They seem

to aggravate and increase the glycosuria. A strict meat and green vegetable diet agrees better than any other. Some give milk, others forbid it entirely. He had found in the few cases he had treated that it was impossible to continue for long periods any one diet. The pure skim-milk diet is meeting with much favor. Alcohol and all spirits, except small quantities of light wine or beer, must be forbidden. This regimen alone will lessen the quantity of sugar eliminated, but it is necessary to use in connection with it certain medicinal treatment. The drugs giving the best satisfaction are opium or its alkaloids, ergot, arsenic, and many others. Of all the drugs recommended, codeine has been by far the most satisfactory in Dr. Witherspoon's hands. It was first suggested by Dr. Pavy, of London, and has the great advantage over its sister alkaloid, morphine, in not producing sleep. It is more efficient, less dangerous, and does not produce the troublesome constipation caused by morphine or opium. Next to it the speaker would place ergot for its physiological effect upon the walls of the blood-vessels. Recently sulphonal and antipyrine have been used with reported good results. He had never used antipyrine in this disease, for the reason that it is recommended in from 30 to 60-grain doses. He did try sulphonal in 10-grain doses, three times a day, and in two days it produced so much giddiness and sleepiness that he discontinued it. He had only used arsenic as an alterative tonic after the sugar had disappeared from the urine. With this treatment the patient should be advised to take light exercise, always short of fatigue, and his living rooms should be good and well ventilated. Alkaline carbonated waters are often of great utility.

Treatment of Strictures of the Male Urethra.—This was the title of a paper read by DR. J. W. HANDLY, of Nashville. He said that strictures of large calibre, if they be recent, but poorly organized and of the linear variety, may be treated by dilatation, which must be continued for months. But should the stricture be densely fibrous, and not easily dilatable, the cutting operation becomes necessary, for which purpose he prefers the Otis improved dilating urethrotome, with which the surgeon can accurately divide any stricture to any size desired.

Strictures of small calibre, situated in advance of the bulbo-membranous junction, unless seen very early, and found to be unusually soft and dilatable, furnish a typical condition for internal urethrotomy, that in which it is attended with the least possible danger and greatest prospect for a permanent cure. Should the contractions be so great that the Otis urethrotome cannot be used, he had found Banks's whalebone dilators, which are made in four sizes, of great advantage in opening the canal so as to admit of the urethrotome.

Strictures of small calibre posterior to the bulbo-membranous junction require a very different course of treatment, since internal urethrotomy at this point is often attended with profuse hemorrhages, fever, rigors, or other disturbances equally as disagreeable. Strictures of this variety, permeable only to filiform bougies, may be treated in one of the four following ways :

1. After the filiform bougie has been introduced it may be allowed to remain *in situ* for two or three days, and another passed alongside of it to serve as a guide for the introduction of a tunnelled sound, later to be followed by the ordinary soft or steel bougies. This is good and safe surgery in the absence of retention.

2. The surgeon may attempt to conduct a tunnelled sound over it at once, to be followed by gradual dilatation.

3. He may conduct over it a grooved staff and then proceed to the performance of external urethrotomy. Or,

4. He may use the staff as a guide for the Maisonneuve urethrotome, and may immediately perform internal urethrotomy.

Officers for 1892.—The following officers were elected for the ensuing year : *President*—Dr. J. W. Penn, Humboldt ; *Vice-President for Middle Tennessee*—Dr. J. A. Witherspoon, Columbia ; *Vice President for East Tennessee*—Dr. C. E. Ristine, Knoxville ; *Vice-President for West Tennessee*—Dr. C. H. Lovelace, Dukedom ; *Secretary*, Dr. D. E. Nelson, Chattanooga ; *Treasurer*—Dr. J. P. C. Walker, Dyersburgh.

Next place of meeting, Knoxville, on the second Tuesday in April, 1892.

Medical Items.

THE MEDICAL LEGISLATION OF NEW YORK IN 1891.

(Special to the MEDICAL RECORD.)

Albany, May 10th. The Governor has just signed the bill (Chapter 311) introduced by Senator Jacobs and Assemblyman Cooney, amending the Medical Examination Act of 1890, by making Section 11 read as follows : "This Act shall not apply to any student who duly matriculated in some legally incorporated medical college before the 5th day of June, 1890, provided that such student within three months after the enactment of this amendment shall file with the Secretary of the Board of Regents of the University of the State of New York, a certificate setting forth the fact of such matriculation, verified by the applicant, and signed by the secretary of the faculty of the college in which he matriculated. "As originally introduced, this bill also exempted those who began the study of medicine with some legally authorized physician prior to the 5th day of June, 1889 ; and provided that, instead of the signature of the secretary of the faculty of the college in which the student matriculated, there might be sent the affidavit of the physician under whom he began the study of medicine, setting forth the time when such student began such study.

This Amendment is to take effect immediately. In signing the Act Governor Hill filed the following memorandum :

"This Bill seems to be a reasonable and proper measure. On June 5th of last year I cheerfully approved the Act which provided for the creation of Boards of Medical Examiners, which Act was intended to pave the way for the establishment of a higher standard for practitioners of medicine to be thereafter admitted. There was considerable opposition to the Bill at the time, but such opposition was not permitted to prevail. Through inadvertence, it must be assumed, last year's bill omitted to except from its provisions those students who had duly matriculated at some medical college prior to the passage of the Act. This simply supplies that omission. The amendment is deemed entirely reasonable. Had my attention been called to the subject last year, I should have insisted that such students should have been exempted from the provisions of the new Act. The course suggested is not without precedent. When in 1871 new rules and regulations were established for the admission of law students, the Legislature subsequently, by repeated acts, expressly exempted from its provisions certain classes of students who had already entered law schools, or who had regularly entered upon their law studies, prior to the enactment of the law. (See Chapter 417, Laws of 1877 ; Chapter 126, Laws of 1878 ; Chapters 35, 257, and 349, Laws of 1879 ; Chapter 58, Laws of 1880 ; and Chapter 25, Laws of 1881.) These precedents are exactly in point. The Court of Appeals recently established new and additional rules for admission to the bar, but in the very order providing for the change it declared that the new rules should not apply to law students who had previously filed their certificates and were actually engaged in their studies. (See recent rules of Court of Appeals.) This seems to be just and fair in reference to law students, and we can see no good reason why the same equitable principle should not be applied to medical students who had acted in good faith, and who may be said to have ac-

quired certain 'vested rights,' prior to the Act of last year. The present Bill does not deserve the criticism to which it has been subjected. It is based upon a correct principle, and I can discover no good reason why it should not be approved."

The Governor has also signed a bill, introduced by Senator Robertson and Assemblyman Fish, declaring that as the Trustees of the College of Physicians and Surgeons in the City of New York, have arranged with Columbia College in said city to assume the instruction now given by the said College of Physicians and Surgeons as a department of the work of Columbia College, they are hereby authorized and empowered to grant, convey, assign, and transfer all real and personal property of which they as such Trustees are seized or possessed, to the Trustees of Columbia College, in the City of New York, upon such terms, conditions, or limitations as may be agreed upon between the two institutions. The Regents of the University of the State of New York, upon being satisfied that the Trustees of the College of Physicians and Surgeons have conveyed and transferred all their property, pursuant to the authority hereinbefore conferred, may accept a surrender of the charter heretofore granted by the said Regents to the said College of Physicians and Surgeons, and forever discharge the said Trustees from their trusts in the premises.

The only medical bill now in the hands of the Governor, and not yet signed, is one introduced by Senator Sheard and Assemblyman R. P. Bush. As there is no opposition to this, the bill might as well be considered a law. It appropriates $5,000 on vouchers duly authenticated by the regents of the University, for the necessary expenses of providing suitable shelving and furniture to receive the medical library offered to the State by the Albany Medical College, and for the necessary expenses of shelving, arranging, and cataloguing the said library. The said medical library shall be a part of the New York State Library, under the same government and regulations, and shall be open for consultation to every citizen of the State at all hours when the State Law Library is open, and shall be available for borrowing books to every accredited physician, residing in the State of New York, who shall conform to the rules made by the regents for insuring proper protection and the largest usefulness to the people of the said medical library.

A bill introduced by Senator Collins and Assemblyman Green never went beyond the Committees of the Senate and the Assembly. It amended the Medical Examination Act of 1890 so as to provide a board of medical examiners for the State of New York, to consist of fourteen members, each of whom shall have received the degree of M.D. in course from a legally incorporated medical college, authorized to confer such degree, and shall have practised medicine or surgery under the laws of this State for not less than ten years. The board of regents of the University of the State of New York shall appoint said medical examiners from a list of nominees to be jointly submitted by the faculties of Cornell University, Columbia College, Union University, the University of the City of New York, the University of Syracuse, the University of Rochester, Niagara University, and Colgate University, or such as shall join in such nomination. The faculties of each of the said universities shall be invited by the Board of Regents of the University of the State of New York to appoint from their own number a delegate to attend a conference for the purpose of making such nominations, at such time and place as the said regents may designate. The number of nominees thus submitted shall be not less than twice the number of examiners to be appointed, and shall comprise, in equal numbers, persons specially selected for their respective competence as examiners in the subjects hereinafter named, and the subject for which each nominee is recommended shall be stated in the list of nominations. The said Board of Regents may remove any examiner for neglect of the duties required by this act, or for malfeasance of any kind, and shall fill any vacancy caused by removal, death, or resignation, by the appointment from a list of nominees to be submitted by the remaining examiners, or an examiner for the unexpired term in the vacant subject. There shall be two examiners in each subject who shall serve for the term of four years, with the exception of those first appointed, of whom one shall serve for two years, and the other for four years, and the said Board of Regents shall in their first appointment designate the number of years for which each examiner shall serve. The appointment of successors to those examiners whose terms of office will expire on September 1st in each second year, shall be made by the said Board of Regents during or before the month of July preceding such expiration of terms of office, either upon the same conditions as hereinbefore specified for the first appointments, or upon nominations to be made by the remaining examiners, as the said Board of Regents may deem expedient.

It was further provided that examinations for a license to practise medicine and surgery shall be conducted both by writing and orally, and shall include practical tests in subjects to which these are applicable. The subjects for examination shall be: 1, anatomy; 2, physiology, including medical chemistry; 3, pathology, general and special, with diagnosis; 4, surgery, including surgical anatomy and clinical surgery; 5, obstetrics, including diseases of women and infants; 6, hygiene, personal and public; 7, toxicology, or pharmacology, omitting any reference to methods of practice or therapeutic doctrines. Any medical college which fails to give adequate instruction in all the above-named subjects shall be excluded by the Board of Regents from recognition as qualifying its graduates for their license. Upon the production of satisfactory evidence of a proper course of study, the applicant must pay $35 into the treasury of the University of the State of New York before he is given an order for examination by the Board of Medical Examiners. The names of unsuccessful candidates are not to be kept for reference in the public records of the University. The Regents shall have power to revoke any such license on evidence satisfactory to them of infamous conduct or malpractice on the part of the person to whom it was issued. Such license, unless so revoked, shall confer authority to practise medicine, surgery, or obstetrics, throughout the State of New York. Physicians and surgeons who live in other States bordering upon New York may enter this State for a distance not exceeding ten miles simply to practise; but they shall not open an office unless they have a license.

An unsuccessful attempt was made by Senator Stadler and Assemblyman R. P. Bush to amend Chapter 280 of the Laws of 1887, amending the several former acts for the promotion of medical science, so as to allow to medical schools the same privileges for procuring bodies that are allowed to medical colleges. This bill came from the Post Graduate Medical School and the New York Polyclinic, and what they asked was to be allowed by law what they were now granted by favor, claiming that it was only necessary to secure this by re-establishing the law of 1882. The bill was opposed by the President of Columbia College and others.

A bill, by Senator Cantor, to regulate the practice of dentistry, was killed in the Assembly. This required all dentists to be twenty-one years of age, and to be licensed by the Board of Censors of the State Dental Society for the judicial district in which the license was given. The object was to give young dentists a better chance to work for themselves.

Senator Fassett did not succeed in having passed an amendment to Section 834 of the code of civil procedure, enabling physicians to reveal professional facts to heirs. More fully stated, this bill provided that a person, duly authorized to practise physic or surgery, shall not be allowed to disclose any information which he acquired in attending a patient in professional capacity, and which was necessary to enable him to act in that ca-

pacity. In case such patient shall have died before the hearing or trial, his administrators, the executors named in his will, any of his next of kin or heirs at law, or either of the persons aforesaid, may waive the foregoing provision; but in the event the testimony thereupon offered or given, in the opinion of the court shall directly tend in any way to disgrace such patient, it may be excluded or stricken out on motion of any of the parties to the action or special proceedings in which it is given.

Assemblyman Gorman tried to strike a blow at patent and proprietary medicines by a bill which never went beyond the Assembly committee on the judiciary, providing that it shall hereafter be unlawful in this State for any manufacturer or dealer in patent and proprietary medicines to sell or offer the same for sale, unless the bottle or package which contains the same shall bear, plainly printed on a label thereon, the ingredients of which the said medicine is composed. All goods manufactured and packed prior to the passage of this act are exempted from the provisions of this act. Any manufacturer or dealer who shall violate any of the provisions of this act, shall be deemed guilty of a misdemeanor, and punished by a fine of not more than $50 for each offence in the case of retail dealers, and in case of manufacturers by a fine of not less than $500, nor more than $1,000, for each offence. The terms "manufacturer" and "dealer," as used in this act, shall be deemed to include any firm or corporation doing business as a dealer in, or manufacturer of, the articles mentioned in this act. It shall be the duty of any board of health in this State, cognizant of any violation of this act, to prosecute any person, firm, or corporation which it has any reason to believe has violated any of the provisions of this act, and the court or officer receiving the fine under any conviction under this act, after deducting the costs of trial and conviction, shall pay the sum over to the board of health prosecuting the case. In case such offence is not prosecuted by any board of health, the fine received shall be disposed of in the manner now provided by law.

Senator Ives had as little success with a bill providing that the Medical College Laboratory of the City of New York, a corporation created by the Act, Chapter 125 of the Laws of 1883, may acquire from its members, upon such terms as may be mutually agreed upon, the several individual shares of such members in the property of such corporation, and thereafter, subject to the special provisions of such agreement, any and all interest of any member of said corporation in its property shall cease to be a proprietary right, and shall not in any sense continue after his membership shall have ceased by death, resignation, expulsion, or otherwise. The directors of said corporation, at any time after such acquisition of all such individual interests as aforesaid, may devote any or all of the property of said corporation (subject and pursuant to the terms of such acquisition) to educational and scientific purposes; and to that end may enter into agreement with the University of the City of New York for the use of such property, and they may at any time in their discretion convey and transfer, by deed or gift to the said the University of the City of New York, any or all of the property of the said corporation, provided that no right of any creditor shall be thereby impaired.

Assemblyman Guenther, also without success, tried to amend the Erie County Pharmacy Act of 1884, so as to extend its provisions for the sale of poisons to places of one thousand inhabitants and over; and also to provide that it shall be unlawful for any person to open or carry on such pharmacy or store elsewhere, within said county, unless such person shall be, or shall employ and place in charge of said pharmacy or store, a registered pharmacist or assistant pharmacist, within the meaning of this Act, except as hereinafter provided.

The Assembly killed Assemblyman Peck's bill to establish a State Board of Veterinary Examiners, and to regulate the practice of veterinary medicine and surgery throughout the State of New York. This bill provided that the Governor shall appoint 7 veterinarians, each of whom shall hold a certificate of graduation from an incorporated veterinary medical college or university, to be selected from a number not exceeding 15, as follows: 5 nominated by the New York State Veterinary Medical Society, 5 by the New York County Veterinary Medical Society, and 5 by the Long Island Veterinary Medical Society; and their successors shall be appointed in like manner. The seven members thus appointed shall constitute the State Board of Examiners in Veterinary Surgery. Anyone who has practised or studied for two years may be examined. Students in college who had entered before July 1, 1891, are exempt from examination; and also all graduates of State veterinary schools. Anyone who has practised veterinary surgery for ten years can retain the title of veterinary surgeon; but anyone who has practised less than ten years shall have the title of farrier. Applicants holding a diploma or certificate of practice from an incorporated veterinary college or university in this State shall pay $10 upon making such application, and $5 upon receiving such certificate.

A Death from Tight-lacing is reported in England. The victim was a laundress, twenty-two years of age, living near London, whose head had been turned by complimentary remarks upon her trim figure, and who died in consequence of her efforts to render it even more trim.

They Want to Get Away.—The advertising columns of our esteemed contemporaries in St. Louis are devoted largely to the seductive representations of different railroad companies, showing how the citizens of that growing town can most speedily, and at least expense, get out of the city. It is perhaps a natural desire.

Immunity Against Influenza Furnished by Vaccination.—Last year the island of Madeira suffered from a double invasion of small-pox and influenza, and many people took the precaution to be revaccinated. Dr. Goldschmidt, a practitioner on the island, was struck by the fact that vaccination seemed to afford immunity against the influenza, and was led to investigate the matter to see if there actually was any relation of this sort between the two diseases. He found that no one of one hundred and twelve individuals upon whom revaccination had been successfully performed suffered from influenza, and of ninety-eight persons, in whom the revaccination did not take, only fifteen had any symptoms of the disease. In an isolated villa there were twenty-seven inhabitants, of whom twelve who were vaccinated escaped the disease, while the fifteen who were not vaccinated all suffered from a visitation of the grippe. Dr. Goldschmidt explains in this way the immunity generally enjoyed by young children in epidemics of influenza, believing that it is due to the influence of the first vaccination, which has not yet had time to become dissipated.

A Royal Paralytic.—Tippu Tib, the African chieftain, has had an apoplectic attack, in consequence of which he now suffers from paralysis of the right arm.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending May 9, 1891.

	Cases.	Deaths.
Typhus fever	1	0

SPONTANEOUS (NON-INSTRUMENTAL) ACCESS OF BACTERIA TO BLADDER, AND SLIGHT VESICAL INCOMPETENCE, AS CAUSES OF CYSTITIS, ESPECIALLY IN THE FEMALE;

WITH REMARKS ON TREATMENT OF THE RESULTING DISEASE.

BY R. VAN SANTVOORD, M.D.,

NEW YORK.

THAT inflammation of the bladder is frequently caused by the introduction into it of bacteria, especially when dilated by the use of foul instruments, is generally known. That vesical inflammation may be caused by similar agents in persons into whose bladders instruments have never been passed, is a postulate in support of which a few clinical facts have been put on record, but which has not, apparently, attracted much attention. In the following paper it is proposed to give a short review of the literature bearing on the subject, and to submit the histories and a short discussion of some cases of the writer's which first called his attention to the matter.

At the outset of the study of this subject the question naturally arises as to whether or not bacteria may not be normally present in the urine. This question has been answered in the negative by Leube,[1] who, after collecting the urine in twenty instances from healthy males, under strict antiseptic precautions, and failing to obtain any result by culture experiments with the urine thus obtained, concluded that "the normal human urine contains neither bacteria nor their germs."

The conceivable channels through which bacteria may reach a bladder whose walls are intact, are by way of the blood- or lymph vessels directly or through the kidneys on the one hand, or through the urethra on the other. It has been apparently proven that the germs of a number of infectious diseases are discharged with the urine, which obviously reach the bladder in the former way.[2] It is not with these, however, that we are at present concerned. In the cases about to be cited the symptoms were associated with rods and cocci not distinguishable by the usual microscopic examination from those seen in all decomposing urine. It seems most probable that in these cases the bladder was reached, especially in women, through the external passages.

The following is a brief *résumé* of the literature which I have been able to find relating to the subject clinically. Sir Henry Thompson mentions a case in which he found the urine loaded with bacteria, although the patient, a male, had never been catheterized.[3] A case of repeated attacks of painful micturition resulting apparently from ammoniacal urine, containing enormous quantities of micrococci of various kinds, in a man who had previously suffered from gonorrhœa and cystitis, but who stated that an instrument had never been passed on him, is recorded by von Jaksch.[4] Schottelius and Reinhold[5] record a case also in a male, aged forty-five, not preceded by any infectious process except measles, or by use of any instrument, in which numerous bacilli were found in the urine. The only literature that treats the subject fully, that the writer has been able to find, is a paper read by Dr. William Roberts before the International Medical Congress in 1881.

Dr. Roberts gives the histories, first, of five males and two females, in only one of whom an instrument had ever been passed into the bladder. In that case it was done a number of years before the development of the symptoms for which he came under treatment. In all, symptoms of greater or less vesical irritation existed. In all, bacteria were found in the freshly-passed urine. Although in some cases the urine smelt badly when passed, in no case was it ammoniacal.

A marked peculiarity of this whole group of cases was that the urine, though turbid on being passed, largely from the presence of bacteria, settled clear and remained so for some days. All the cases, except one which was not treated, were cured or greatly improved by salicylate of soda, in doses of twenty or thirty grains given two or three times daily. In all, the cure or alleviation was accompanied by the disappearance or great reduction in the number of the bacteria.

Dr. Roberts made the following comments on these cases: "The circumstance that the organisms do not multiply in the urine after emission, points to the conclusion that their seat of development is not the urine itself, but some portion of the mucous membrane of the urinary tract. This form of bacteriuria is manifestly a different condition from that in which the urine becomes ammoniacal within the urinary passages, and which is presumably due to the micrococcus uriæ. It is also different from that phase of incipient decomposition through which all urines exposed to the air pass on the way to ammoniacal decomposition. In incipient decomposition, as in non-septic bacteriuria, the urine is opalescent and swarms with bacteria, but I could not distinguish, by their structural character, the organisms in the two contrasted conditions.

"The precise relations between the organisms and the symptoms in these cases require further elucidation. In women this condition may certainly exist without producing symptoms, or only a slight increase in the frequency of micturition. It is also seen in Case III. that the urine continued to manifest the presence of bacteria, though not in large numbers, after the symptoms had entirely passed away. If it be assumed that, in these cases, a colony of bacterial organisms becomes established in or on some portion of the urinary mucous membrane, it is probable that the symptoms would vary in kind and intensity according to the exact seat of the colony and the degree of activity of the growth going on in it." The doctor called attention to the fact that the histories of his cases did not support the view that in all cases the irritation of the urinary passages originates from bacteria. This was in some cases secondary, keeping up the symptoms. The mode of access, whether by the circulation or by the urethra, he regarded as doubtful; the latter, however, seemed probable in woman. The administration of salicylate of soda was followed by good results too frequently to admit of the supposition that its effects were only apparent, the recoveries being, in fact, spontaneous.

A case of bacteriuria is cited by Dr. Roberts at the close of his paper, in which the urine resembled in all re-

spects a urine which had become turbid from incipient decomposition, *i.e.*, it swarmed with bacteria and did not become clear on settling. The salicylate of soda had not the slightest effect on this patient. He narrates also the history of a healthy-looking boy of three years of age, the subject of recurring hæmaturia. The urine was al ways crowded with micrococci, singly, in pairs, or in masses. There were no rods. The urine was sometimes acid, sometimes alkaline. Urination was neither painful nor frequent.

My own first case was that of an active woman about sixty years of age, who had suffered for several months from vesical tenesmus, without much pain. She had never had any bladder trouble before, and had never had an instrument passed into that organ. She was fond of good living and sweets, had recently recovered from some undetermined variety of pain in one arm under the influence of a lithia salt, had had chills and fever, and applied to me for treatment on account of aching pains in the sacral region shooting into the legs. These disappeared promptly under quinine, and her vesical symptoms reappeared. The urine was found to contain a small amount of pus and numerous bacilli, the latter being present, in a sample examined within an hour of its being passed, in quantities too large to be accounted for by accidental contamination. Citrate of potash and broom-corn seed tea produced no alleviation of symptoms. The salicylate of β-naphthol was then given in five grain doses four times daily, this dose being increased to ten grains four days later. The symptoms were almost immediately lessened. In eleven days they had disappeared, as had also the bacilli. Two weeks later a recurrence took place, which the patient treated herself, without consulting the writer, with the same remedy. Again a cure was effected, and no further recurrence took place until the present month, an interval of over two years. As before, excessive tenesmus was complained of, but the bacteria in a fresh specimen of urine were probably not more than could be accounted for by accidental contamination after the urine had left the bladder. Complete relief followed the administration of betol and hydrochloric acid, the latter being given on account of dyspeptic symptoms.

This case seemed in many respects parallel to those reported by Dr. Roberts, though I did not note whether the urine settled clear when fresh, not at the time having read Dr. Roberts' paper. The betol has an advantage over the salicylate of soda in being much better tolerated by the stomach. The absence, however, of evidence of bacteriuria in the last attack would seem to show that the organisms had nothing to do with the symptoms. The condition of the urine in this case did not explain the symptoms; it was not concentrated, did not contain irritating deposits, and only a very little pus. The relief from the betol seemed too marked and immediate to be accidental. I could only suppose that the urine did contain some unknown irritant, due, perhaps, to the patient's faulty digestion, and that this was corrected by the betol.

My second case is one of ordinary catheter cystitis, which I cite for reasons which will appear later. It occurred in the person of a man aged fifty-five, whose bladder became infected by a catheter which was imperfectly cleansed by a careless nurse, his urine having to be drawn on account of retention during typhoid fever. Betol in five-grain doses was given early in this case, but was discontinued because it seemed to disturb the stomach. The bladder was washed out for a while, various substances being used, *i.e.*, borax, boric acid, hyposulphite of soda (recommended by Tait), and bichloride of mercury 1 to 10,000. The latter especially proved to be intensely irritating, possibly because some of it was left in the bladder. Internally citrate of potash was given. The urine meanwhile fluctuated in its opacity. The washing out of the bladder was very painful to the patient, and as no satisfactory progress was being made it was stopped, and betol, in five-grain doses four times daily, was again given with the citrate of potash. In twenty-four hours the urine was clear and all symptoms of irritation gone. In the earlier course of this case the betol had had no appreciable effect. I am inclined to think that during the treatment the vesical walls had been regaining their tonicity, and that perhaps the stimulation furnished by the painful injections contributed to this result. When finally the bladder became able to thoroughly expel its contents and artificial irritation of its walls was suspended, it got well spontaneously. Feltz and Ritter found that when the micrococcus uriæ was injected into the healthy bladders of dogs it was soon eliminated.[1] The use of unclean catheters is not always followed by cystitis.[2] It would seem that in all probability some previous lesion of the bladder, especially dilatation of that organ, was necessary in order to enable bacteria of the varieties under discussion to obtain a foothold.

In the above cited case I happened to be examining the urine daily before the cystitis developed, as the patient had a slight typhoid nephritis. Beyond this there was no evidence of disease in the genito-urinary organs prior to the catheterism. Dilatation of the bladder, due to retention following a small dose of morphia, was clearly the factor which rendered it possible for bacteria to secure a foothold in the organ.

The third case which I wish to present was the following: The patient was a lady about forty years of age. Her general health had always been good, except that she suffered from constipation and occasional attacks of indigestion. Fourteen years before her present attack her water was drawn after a confinement, but no instrument had ever been passed since that time. Five years before she had noticed that her water came away on sneezing or coughing, no confinement having taken place since the above mentioned. She had noticed that her urine was turbid for some months before the development of acute symptoms. She was accustomed frequently to go for many hours without emptying the bladder, that organ having finally become so insensitive, apparently as the result of training, that she was accustomed usually to relieve it from a sense of duty, not from any pressure, except that she was obliged to get up once in the night. I was called to see her on account of frequent and painful micturition following an exhausting shopping tour. The urine was turbid, alkaline, and, when examined five hours after being passed, contained triple phosphates. I regarded this as evidence that the urine was ammoniacal when passed, until I read of a case of myelitis of Leube's[3] which was supposed to have been passing ammoniacal urine for three months, because it was found to be ammoniacal within two hours after being passed; notwithstanding this, a fresh specimen drawn by a catheter was found to be acid and clear. This case is a warning against being too quick to draw conclusions from the condition of urine not examined immediately after being passed. In my patient the urine was always turbid, and the turbidity was always largely due to bacilli and cocci, the deposit of pus, at first considerable, being quickly reduced to a small amount. As many specimens, some being drawn by a catheter into a clean bottle, were examined within two hours after being voided, I am confident that I did not deceive myself as to the bacteria being present in the bladder. As no instrument had been used for fourteen years, it seems most probable that they had found their way into the bladder spontaneously. In addition to the dribbling of water on coughing and sneezing—a symptom which developed nine years after her last confinement, and which was not therefore the slight incontinence that often follows pregnancy—the patient stated that the urine came slowly and with some effort. I also found on one occasion, after the bladder had been emptied as thoroughly as possible by the patient, that the catheter brought away about half an ounce of urine more. The case, therefore, appeared to be one in which a mod-

[1] Gradle: Bacteria and the Germ Theory of Diseases, p. 69.
[2] Von Jaksch: Klinische Diagnostic, p. 192.
[3] Zeitschr. für klin. Med., 3, 233, 1881.

erate amount of dilatation of the bladder had been caused by the patient's habit of retaining her urine sometimes from morning to night. The turbidity of the urine, noticed some months before acute symptoms set in, may well have been due to the presence of bacteria whose intravesical propagation was rendered possible by the incomplete emptying of that organ. The case was, then, one of a variety mentioned by Dr. Roberts, *i.e.*, a bacteriuria without symptoms of vesical irritation until unusual exertion brought on an acute attack of inflammation, to which the dilatation and bacteriuria were apparently related as predisposing causes. In citing the reasons for disappointment in relieving symptoms after removing stone from the bladder, Sir Henry Thompson mentions the failure to regularly withdraw residual urine, one to one and one-half drachm having been found to be sufficient to give trouble. From this it is evident that a slight amount of vesical incompetence may be a serious matter.

The condition of my patient's bladder was strikingly suggestive of that of the rectum when similarly neglected. As a case similar to, though not so severe as, the above, shortly afterward presented itself, it has occurred to me that this sequence of events, viz., neglect to empty the bladder as often as it should be, slight incompetence from repeated slight over-distention, and spontaneous bacteriuria, might be much more common factors in the development of cystitis than the literature of the subject would lead one to suppose. In this case the urine, with one or two exceptions, never settled clear. It belonged, then, to Dr. Roberts' variety in which the urine, as passed, resembled urine undergoing decomposition.

In the treatment of this patient it was an easy matter to control symptoms by rest, belladonna, milk diet, and washing out the bladder, and to cause the pus to disappear. To produce any permanent impression on the bacteriuria was found to be quite another affair. Internally, betol in 20-grain doses every three hours; salicylate of soda, gr. xx., t.i.d.; salol, gr. x.; quinine, gr. ij., every three hours; saccharine, gr. x., t.i.d.; boric acid, gr. x., t.i.d., were all tried with no very definite effect. The saccharine for a time seemed to reduce the turbidity of the urine, the urine on one occasion settling clear; but the effect was not permanent. Solutions of nitrate of silver and sulphate of zinc, each two grains to the ounce, were used as vesical injections, once daily, and left in until they caused slight irritation. These solutions, mixed in a test-tube with the urine from this same patient, would precipitate all bacteria. Their effect, when used in the bladder in clearing up the patient's urine, was very slight, the urine next day not being as clear as after the use of a two grain to the ounce acetate of lead solution, which, when mixed with the patient's urine in a test-tube, showed very little power to control bacterial growth. Such attempts, in fact, were not very rational, if my ultimate view of the case was the correct one. To destroy the bacteria in the bladder by any means could have only a temporary effect if the fundamental dilatation persisted, and the bacteria could again find access from outside to the residual urine as soon as treatment was suspended. The recommendations of drugs for the disinfection of the urinary passages by internal medication are, as a rule, rather vague. My own experience in this case bears out Dr. Roberts' as to the uselessness of the salicylates as well as the other agents tried in this variety of bacteriuria, though boric acid was the only one which did positive harm in disturbing digestion.

With regard to bacterocidal injections, they can be of permanent use only if they destroy all the bacteria present, and means can be taken to prevent a new invasion. The fact seems to be that this is very difficult to do. A strong solution of nitrate of silver causes necrosis of epithelium and coagulation of mucus which may not have been previously washed out, or may have been secreted during its use. These bits of coagulated tissue protect germs from the action of the agent. The necrosed tissue and the depression of vitality of still living elements of the bladder-walls afford a most favorable opportunity for the rapid growth of the undestroyed germs. The foulest specimen of urine passed by the above-quoted case of catheter cystitis was after the use of a $\frac{1}{10000}$ solution of bichloride of mercury. Fürbringer,[1] it is true, claims to cure the most severe cases of catheter cystitis in from one to two weeks, by flushing the bladder twice daily with one or two litres of a $\frac{1}{5000}$ solution of bichloride of mercury. He uses a glass catheter, which can readily be kept clean, and allows the bladder to empty itself after being filled, *i.e.*, he does not restrict the amount of fluid allowed to flow into the bladder. He allowed the bladder to empty itself entirely after the use of the injection, and possibly it is owing to the shortness of contact of the mercurial solution that no irritating results seem to have followed. It would be of interest to know the condition of these cases some months after they had been cured by such free distention of the bladder as seems to have been employed. As the cases were acute, it is possible that no residual incompetence was left behind.

Tait claims that excellent results follow the use of hyposulphite of soda solution in catheter cystitis. I found that five per cent. of hyposulphite of soda in normal urine did not prevent it from swarming with bacteria in a few hours. It seems probable that the mechanical washing out of the bladder and the dilution of the residual urine—for the repeated injection and outflow of fluid from the bladder simply dilutes and does not entirely remove its original contents—keeps the urine from being very irritating, while the bladder-walls are recovering their contractility. The almost, if not quite, inert hyposulphite of soda does this quite as effectually as any other fluid. If a powerful disinfectant is not well tolerated, as in the case above cited, it is simply worse than useless.

The radical treatment of such a case resolves itself, therefore, into the cure of the vesical incompetence. Under this heading should first be mentioned certain things which are often done, which are apt to increase the evil. The use of narcotics is to be avoided as far as possible. Belladonna is especially cautioned against by Sir Henry Thompson. I have above suggested that the vesical irritation set up by an acute attack of cystitis may prove of benefit, by exciting vesical contraction and so relieving an existing muscular incompetence of the organ. While these agents may be indispensable in acute suffering, their effects should be carefully watched and not pushed to complete relief of tenesmus. It was part of the writer's early medical education to believe that the proper way to wash out a bladder was to use a sufficient amount of fluid to distend the organ, in order to unfold it and bring the injected fluid into contact with the whole surface. Such practice tends directly to dilate the bladder. Many authorities, such as Skene and Sir Henry Thompson, advise the use of very small injections, one or two ounces. If it can be accepted as true that even a slightly dilated bladder, especially in the female, can become spontaneously infected with bacteria, the great importance of respecting this caution is doubly obvious.

The internal remedies most used for vesical atony are strychnia, which is supposed to increase the sensitiveness of the vesical innervation through action on the spinal cord, and cantharides, which acts by irritation of the vesical mucous membrane. In the above case the latter drug, given in two-drop doses, afterward increased to five, would temporarily check the tendency to dribbling on coughing, but no permanent effect was produced. An attempt was made to have the bladder systematically catheterized and entirely emptied every evening, the husband being instructed in the passage and disinfection of the catheter. This resulted in nothing but the setting up of some irritation at the vesical neck, no improvement in the urine taking place. On considering this procedure, it is easily seen that it is not as easy to fully empty the bladder in the female as in the male. In the latter the residual urine is collected behind the prostate, where it is readily accessible

[1] Deutsche med. Wochenschr., No. 20, 1883.

to the catheter. If a partially distended bladder is examined in a reclining female cadaver, it will be observed that it hangs over on either side of the uterus in such a way that, when a catheter is introduced in the usual manner, the central portion of the vesical wall comes in contact with the instrument before the urine has all been evacuated, leaving an accumulation of urine on either side of the uterus. Ordinary catheterization does not, therefore, empty a relaxed female bladder, even when no abnormal adhesions or dislocations of organs exist. It is possible that, by placing the woman on her side and introducing a curved instrument into the dependent portion of the bladder, a complete evacuation could be secured by syphonage. In the case under discussion it was finally proposed to use electricity to restore the full contractility of the bladder. As, however, the patient had been rendered comfortable by the measures already employed, although still passing urine turbid with bacteria, she declined any further treatment. When last heard from, a number of months after cessation of all medication, she was still comfortable.

My fourth case, that of a lady about thirty-five years of age, had had bladder trouble with two confinements, fourteen and four years before present illness. She never had had an instrument passed into the bladder. For a long time she had complained of gushes of urine on laughing, and for a month before acute symptoms of vesical trouble developed she had to pass water somewhat more frequently than usual, and had to respond to the call quickly to avoid involuntary micturition. She had noticed that the urine smelt "strong" for some time, but did not know whether it had been turbid or not. Following a slight exposure, micturition became more frequent and painful, especially at the end of the act. No cause for bladder trouble previous to this final acute exacerbation could be determined. The urine was found to be turbid, alkaline, and containing, besides pus, numerous bacteria within two hours of its passage. The acute symptoms subsided under rest, broom-corn seed tea, and moderate doses of belladonna, but the urine did not improve. Betol, in ten-grain doses every three hours, produced no effect on the bacteria. The bladder was then washed out on four successive days—first with water that had been boiled, then with a solution of nitrate of silver, gr. ½ to 4 ounces, and again with boiled water, only two ounces being injected at a time, the soft rubber catheter used being boiled after use and kept in 1 to 20 carbolic acid. Under this treatment the pus almost entirely disappeared, the passage of urine became quite normal, both in frequency and painlessness, but there were still rather numerous rods and cocci in the freshly-passed specimen. Tincture of cantharides, 1½ minim, and sulphate of strychnia, gr. $\frac{1}{36}$, were given three times daily. Nine days after the last injection patient was feeling entirely well, and the rods and cocci in the fresh urine were very few in number—not more, in fact, than might have readily found their way in from the vagina, the presence of considerable vaginal epithelium showing the existence of vaginal discharge.

The unpleasant odor the urine had been presenting for some time before acute symptoms of cystitis developed, and the fact that the bacteria did not greatly lessen in amount till drugs were given which tend to strengthen the vesical contraction, can be fairly taken to indicate that, in this case as in the last, some vesical incompetence and spontaneous invasion of the bladder by bacteria had existed, giving rise probably to a low grade of inflammation, which was readily increased in severity by a slight exposure.

I wish to particularly call attention to the probable mode of action of the weak nitrate of silver solution in this case. At the present time, owing to the fact that most or all of the agents which have long been used as local applications in controlling inflammation are bacteriocides of greater or less potency, we are apt to attribute their efficiency to this power. In this case the drug was most potent in controlling the inflammatory exudation, but, as far as could be judged from my rough means of observation, had no immediate effect on the bacteria in the urine. Some observations made in 1889 by R. Henry,[1] on the action of astringents, are suggestive in this connection. On experimenting with astringent solutions of various strengths, he found that very weak solutions caused vascular contraction, very strong ones vascular dilatation and inflammation. Certain intermediate strengths would cause on the one hand vascular dilatation, and on the other would check the migration of white blood-corpuscles. The power of these agents to control inflammation seems therefore due, not to their astringent power at all, that is to their causing vascular contraction, but to their power of influencing the nutrition of the tissue-elements with which they come in contact. In a disease caused by bacteria they may be of service directly, by rendering the tissues less vulnerable to their attacks, and indirectly by preventing inflammatory exudations, which form a good culture medium for those organisms where they exist. It is in this way probably, and not as direct bacteriocides, that all remedies which exert control over bacterial diseases exert their power, except in applications used in certain cutaneous maladies in which the skin is sometimes more tolerant of certain agents than are its parasites. It is a very old matter of experience that, generally speaking, the inflamed bladder does best when treated by mild applications. It is something gained, I think, to fortify this fact of experience by the above-suggested explanation at the present time, when in our efforts to strike directly at the newly-discovered causes of disease, we are apt to forget the effect of our blows upon the patient.

The fifth and last case that I will mention was that of a lady of over seventy, whose urine I examined as a matter of routine, not because she had any vesical symptoms. She stated that it had been "smelling bad" just after being passed. A specimen examined within half an hour after leaving the bladder was found swarming with bacteria. As she showed no symptoms of vesical disease no treatment was directed to the bladder.

The writer was led to study this subject on finding how little was to be learned from readily accessible works on diseases of the bladder on the subject of spontaneous bacteriuria, and from the difficulty which he at first experienced in knowing just what significance to attribute to that condition. It is quite probable that such cases are familiar enough to those who have had much to do with vesical disease, and that they are very common. The habit of holding the urine too long, common among females, is generally commented on and condemned by authors. The importance of vesical incompetence as a factor in the etiology of cystitis is also generally recognized. The suggestions that the writer has to offer are simply that a minor degree of the latter evil is more often present than would be supposed from the literature of the subject, and that the spontaneous access of bacteria to the residual urine in such cases is a common and important factor in disease of the organ, especially in the female. It seems probable that the failure to recognize these factors may explain in a measure the difficulty often experienced in treating even mild cases of cystitis.

106 West 122d Street.

The Fourteenth Annual Report of the New Jersey State Board of Health and Bureau of Vital Statistics for the year ending June 30, 1890, has been issued. It is an interesting volume with a mass of valuable material, reflecting great credit on the Secretary of the Board, Ezra M. Hunt, M.D., LL.D., of Trenton. His several papers and statistics are excellent. The latter show a population of 1,441,017, number of deaths 28,530, or 19.80 per 1,000. Remittent fever claimed 195 victims.

A CONTRIBUTION TO THE CLINICAL USES OF PROFESSOR KOCH'S REMEDY FOR TUBERCULOSIS.[1]

By KARL von RUCK, B.S., M.D.,

DIRECTOR WINYAH SANITARIUM FOR DISEASE OF THE LUNGS AND THROAT, ASHEVILLE, N. C.

Mr. President and Gentlemen: At your request, made at our last meeting, I present to you this evening the results of my experience with Professor Koch's remedy, obtained in this institution after a ten weeks' use upon upward of twenty patients.

In the application of the remedy I departed, even from the beginning, from the teachings and methods observed by me during my stay in Berlin, in so far that I began with much smaller doses, and endeavored to avoid all febrile reactions, increasing very slowly, and allowing longer intervals in their repetition. I found by very frequent physical examinations, both before and after the injections, that local reactions occurred in the lungs without general symptoms, and were followed by the same effects upon the expectoration and other symptoms of the patient, as were witnessed from the remedy under larger doses with general reactions, and the general condition of patients did not suffer.

The local reactions occur frequently within three or four hours after injections, and last a variable length of time; for their recognition very painstaking comparative examinations and diagramic records are indispensable. Although at times left in doubt, I have been able to watch the effect of the remedy upon the lungs so closely, that the local changes were a sufficient guide to the increase of dosage, and I have made the frequent observations of the temperature, pulse, etc., not to demonstrate the action of the lymph, but to guard against the administration of over-doses.

Upon lupus and laryngeal cases, ocular inspection was of course possible, and these cases confirmed the position, that local reactions occur quite uniformly when all fever and general disturbance are absent.

I show you here the temperature charts of a case of lupus vulgaris, upon which you will see no fever curve whatever from the day he received his first injection to the present, and although you can now note the typical local reaction from the 35 milligr. administered this forenoon, you see his temperature is normal and has been so all day.

You will also note that the lupus patch on the right side of his face is entirely healed, showing only a faint reddish blush from his injection to-day, and that the patches and ulcerations upon the nose and forehead are covered with a dry crust, now partially detached, and under which you can see the parts healed over; in the still open ulcer upon the left cheek there are punched-out excavations where the tubercular tissues have suppurated and discharged; everywhere upon this open sore you see also healthy granulations and repair; proving, on one hand, the specific and selective influence of the remedy, and, on the other, that the good results from this method can be obtained without fever. That which you see here upon the face, I will give you opportunity to witness in the larynx, and hope to demonstrate to you in affections of the lungs. The microscopical preparation from this case Dr. Ambler will show you in the laboratory.

Now, I expressed myself when in Berlin, to several of Professor Koch's associates then in charge of the clinical work, that I believed many of the dangerous phases from its use could be avoided by moderating the doses and allowing longer intervals, and that I doubted the utility of any course under which the consumptive patient was made to steadily lose in flesh and strength, and I have also called the attention of the profession in this country to this subject.

[1] Read before the Buncombe County Medical Society, with demonstration of cases at the Winyah Sanitarium, March 2, 1891.

After Professor Virchow had read his first paper, upon the pathological changes observed by him in cases who died subsequent to the use of the lymph, I became even more conservative, and have had since that time no rise of temperature which could be at all suspected as due to the injections. Although it is not to be gainsaid that Professor Virchow in his post-mortem examinations saw only the unfavorable cases, and that the cases who were examined by him were far advanced, and would have died had no lymph been administered, the same as have a number of cases within a month, in my own experience, after I had refused to administer the remedy to them; we cannot ignore the pathological findings of so frequent general miliary tubercular eruptions of recent date, and while, undoubtedly, much closer scrutiny was brought to bear upon these cases by the pathologists who had occasion to examine post-mortem, and while similar conditions have before and since been observed in tubercular subjects who never received the lymph, to the unbiassed observer and student of the reports, a strong suspicion must arise that there is, to certain extent at least, a causal relation, and that under certain circumstances there exist dangers in the method which we must strive to understand, and avoid if possible.

All these dangers granted and understood, the value of the remedy is thereby not impaired, and the good results which we have already seen on every hand, are just as real.

Why, in some cases, the results were curative and were so shown even in post-mortem specimens, by Dr. Virchow and others (tubercular ulcerations had evidently and recently healed); and why a similar healing process was not shown by others, but, on the contrary, intensification of the disease-process being present, remains to be worked out in the future, the same as we have had to do, in our past experience, with other, and on that account, none the less valuable means for the cure of disease. I venture to suggest that at least one way to explain these apparently contradictory results is, that in some cases the tubercular material softened and necrosed more rapidly than it did in others, that by a rapidly induced necrotic process the dangers from absorption of active, infecting bacilli and spores are proportionally greater, and that the extensive broncho-pneumonic developments and general miliary tubercular eruptions are due to such absorption, and extension of inflammations produced by over-dosage.

In a similar process, established more gradually, necrotic processes would occur less frequently, or not at all, and inflammatory changes would effectually close and obliterate the absorbent vessels surrounding the area acted upon, and the danger would thereby be lessened, or altogether avoided.

Other things being equal, the rapidity of such changes must depend upon the intensity of the effect produced by the remedy, and it is fair to presume that the latter depends upon the amount of the remedy which reaches the tubercle in the pulmonary cases as well, as we see it to depend, as in the cases of lupus and other external tubercular affections.

I have purposely said that, "other things being equal" the rapidity of changes and intensity of effect would depend upon the dose administered. It would therefore behoove us further to see wherein certain inequalities existing may modify the effects of dosage. Most important, undoubtedly, are the inequalities for the time existing in the tubercular deposit or eruption itself and in its surroundings. The greater the vascularity in the tissue surrounding the tubercle the more prompt and intense must be the effect of the lymph; thus the miliary tubercle and the encapsuled deposit would have the least chance for being acted upon, whereas the effect would be most intense in deposits surrounded by granulation tissue. Pathological investigations have already proven this to be the case, without, however, offering this, to me, only possible explanation. Indeed, surprise, even doubt in the remedy have followed the demonstrations that

young tubercles or old deposits were apparently not influenced by the preceding injections of the lymph, while at the same time necrotic foci showed the action (perhaps too violent) unquestionably attributable to its use.

Could it not be that, after we have reached a certain dose which we are satisfied produces a local reaction under the continuance, or very slow increase thereof, the more recent eruptions would reach a stage of vascularization, bringing them also within its curative effect, and that only after a certain period of time, say several months, we can safely step to the larger doses, whereby we would have a sufficiency of the lymph within the blood at a given time, so that we could expect to reach the old deposits, which through the sparingly present capillaries in the fibroid capsule surrounding the tubercular focus, did not receive the amount of lymph necessary for the development of its specific action? Would this explanation, together with others to be offered further on, not also account for various anomalies in reactions heretofore observed?

I am firmly convinced that the excessive effects of the lymph are to be scrupulously avoided; we must steer clear of the acute and destructive processes which we see in the ordinary course of the disease, and, as heretofore, their production or occurrence is dangerous, no matter what our method of treatment may be.

Our German colleagues now admit that the dosage heretofore was excessive, inasmuch as they recommend it recently much smaller, and say that general reactions are not necessary. One of the gentlemen who takes this position now would hardly consider with me the propriety of such a course when I suggested it early in December.

The reason why lupus cases bear large doses without such complications is plain enough, when we note that there is nothing in these to hinder the ready discharge of the broken-down tubercular tissue; the conditions are entirely different in the lung, here no external communication may exist at all, and the only curative influence which we could desire upon the living tubercular tissue is pressure-atrophy. No matter how early the stage under such conditions, general reactions, the occurrence of bloody sputum, or hemorrhages, are not only not necessary, but are conclusive evidence that the dose was excessive, poisonous, and dangerous. The fact that in others, and perhaps a majority of early-stage cases, no such dreaded result followed, is no argument in favor of wilful incurrence of such danger.

It is quite possible for me to conceive of a dosage which instead of causing necrosis, would induce only such slight irritative effects upon the periphery of the tubercle or cheesy deposits that we might favor thereby the occurrence of nature's most desirable mode of cure, that is, pressure atrophy of living tubercular tissue, by fibroid or rather connective tissue proliferation and shrinkage, with slow cleaning of cavities and expulsion of tubercular cheesy matter upon exposed surfaces; and I am of the opinion that my dosage is productive of such results.

To show how undesirable necrotic processes induced artificially really are, I need only to call your attention to the great similarity between the classical symptoms of general reaction by Koch's remedy and the symptoms which obtain whenever we have a considerable process of softening and elimination of tubercular deposits in the ordinary course of the disease. Chills, fever, hemorrhages, loss of appetite, vomiting, general malaise, loss in weight and strength, variously associated, one or the other prominent, who does not recognize in them more or less rapid destructive processes of tubercular deposits? Is it not probable that we generate within the body through the agency of tubercle bacilli, the same lymph, or a similar product, that Koch obtains by artificial cultivation of the same germ? Is it not true that when these processes in the ordinary course of the tubercular disease are intense and long continued, our patients are apt to die from exhaustion, or from the occurrence of general miliary tuberculosis, and is not this the more likely an occurrence, when the patient is already much reduced and exhausted when such acute processes set in? When me now have such a case, is it not adding fuel to the already uncontrollable fire, to give large injections of lymph, and have we not already perhaps more of such action which the lymph produces than we feel safe to carry the patient through?

Already the experience with many such patients is decidedly unfavorable in the present mode of use of Koch's remedy, only the relatively strong cases, where the tubercular processes are circumscribed, have been able to stand such treatment. In my judgment, the lymph should be used only in that class of patients in which the acute symptoms have either entirely or at least largely subsided, but never during their height in decrepit patients, and in such not until they have been somewhat restored in flesh and strength by other means at our command.

You might ask me in the discussion, why not let nature do it in all cases, or why induce the changes with the lymph, in an apparently arrested, or in an early stage case?

I answer the question now, and point out to you that the presence of living tubercular tissue is ever a source of danger, as it is constantly undergoing changes which tend to extensions of the process and regularly lead to involvement of previously unaffected lung portions, and that if we can produce its elimination or encapsuling at a time when the patient is at his best in his general condition, if we can prevent his waste by the control we exercise in our dosage and also in his diet and general management, we are unquestionably the gainers.

Under nature's method, only those deposits soften and break down which have, so to speak, become ripe, while at the same time the disease is present in other parts in all its various stages of development; thus softening and repair, extension and advance, go hand in hand, and recur again and again until the patient is finally exhausted, or we succeed by means hitherto employed, in bringing about an arrestment more or less permanent. Even then the slumbering embers are liable to be fanned into activity by incidental occurrences, such as an acute bronchitis, an influenza, or other disturbances whereby the nutritive processes suffer.

This might seem contradictory to what I have said of the impropriety of giving lymph when acute processes are already in existence. Theoretically it might be given with advantage then also, and its use would be justifiable, were it not for the danger of exhaustion before the process is completed, and also the danger of increasing the liability to general infection which already exists; and may be favored by a too rapid destruction and separation of not only the part undergoing such change, but also of other deposits which reach the same stage later.

I do not offer these views with the assertion of their absolute correctness, which would be preposterous at this period of our experience; they are thoughts forced upon me by reflections upon what I have seen, read, and observed in my practice, and I offer them for your consideration and to bring about discussion.

But to come to our clinical results, which I desire more particularly to show you this evening. For this purpose are available twenty-one cases which have been treated a sufficient length of time to justify conclusions of the effects produced. To these belongs the case of lupus vulgaris already referred to, the remainder are all cases of pulmonary tuberculosis, some of them with co-existing tuberculosis of the larynx. According to the stages of disease and physical conditions of these patients they may be divided into three classes: 1st. Cases with moderate local disease and still good physical condition; 4. 2d. Cases with more extensive local disease, presence of cavity, but still in fair physical condition; 8. 3d. Cases with advanced local disease, cavities in both lungs; physical condition one of considerable impairment; 8.

In the first place, I am glad to say we have no fatalities to record. In one case only, when I had increased more rapidly in my dosage than I do now, there resulted a

most undesirable general and extensive local reaction lasting several days, and which cost the patient several pounds of flesh, and me very much anxiety. In three of the four cases of the first class there is no longer cough or expectoration, and in a number of the last sputum-specimens examined, bacilli were absent. Two of the three cases had not lost weight before admission, and have gained but little, one three pounds and the other six pounds, the third case has gained eleven pounds and is still gaining, being yet some fifteen pounds below his normal weight. The subjective symptoms in these three cases are entirely removed, locally some changes in percussion note and in respiratory sounds are still present, but are improved over conditions presented upon admission, and I cannot say that, locally, further changes would be necessary for a cure. The fourth case is one strongly predisposed by hereditary tendencies (the mother having recovered from pulmonary tuberculosis in this institution two years ago, is still well; the sister is a patient belonging to the second class presently to be described, and also here under treatment).

While some improvement is manifest, she still shows marked local reactions to small doses (6 milligr.), and a few bacilli are still in the sputum, this is, however, scant and occurs only after the injections. There has been but slight gain in weight, three pounds I believe.

Three of these cases are ladies, and I could not persuade them to face this audience for examination. The gentleman, a patient of Dr. Loomis, of New York, is here, and you can satisfy yourself in his case of his improvement, comparing his present condition with the records and diagrams of the charts made upon and since his admission. Dr. Ambler will show you in the laboratory the preserved slides from the sputum examinations, and you will be particularly interested in the changes which have occurred; the first slide made on admission is perfectly loaded with bacilli, and in so short a time as a month no sputum is longer available for examination; in the last specimens examined no bacilli were found.

We come now to the second class of eight cases, all of severe type, who have lost considerable flesh, and, with exception of one case, showed slight evening rise of temperature, none, however, can be considered fever patients. The most marked improvement in these cases is manifest in three of them, an example of which you will see in this gentleman, also one of Professor Loomis' patients. As you will note from this diagram of the chest, the shaded portions show the abnormal changes in the right upper, middle, and portion of the lower lobes, and the excavation is marked out showing its extent from the apex to the second rib. Gurgling existed in this cavity, crepitation down to the fifth rib, and harsh inspiration below; similar were the phenomena posterior. On the left side a very small cavity is marked out under the inner third of the clavicle, harsh and interrupted inspiratory sounds extended to the fifth rib, the expiration was prolonged, there were fine râles anterior and posterior; below the angle of the scapula, and below the fifth rib in front, the respiratory sounds were fairly good. This patient received to-day 35 milligr., and there has been neither general nor local reactions. You will note an entire absence of all moist sounds, and the cavity on the right side entirely dry, the respiratory sounds are much smoother than they were, and a superficial examination upon the right side, would, beyond the amphoric respiration over the cavity, detect little change from the normal. The cavity on the left side I can no longer demonstrate, although I have done so several times after his admission. The harsh, interrupted sounds have given place to a softer quality, only you note that the respiratory sounds all over this left portion which is marked out on the diagram, are feeble and less distinct. This patient has gained thirteen pounds in flesh, his expectoration is much reduced, but there are still a few bacilli present. His improvement corresponds with the next gentleman, whose condition both on admission and now, is as nearly identical as it well could be; both show similar located cavities, about the same auscultation-phenomena, and have followed a similar course in every respect, only this gentleman, who received 35 milligr. to day, shows a local reaction in his left lung where this morning every moist sound was absent, now you hear fine crepitation at the end of inspiration over the left side in front and back; you see from his temperature chart that he has no fever, his pulse runs a little higher only. Although bacilli have been absent in his slight expectoration for a week or ten days, I am almost confident that after this local reaction we shall find them in the specimen to be examined to-morrow. He too has gained twelve pounds in weight and says he never felt better in his life.

The next case is a patient of Dr. Conrad, of New York, whom you will also find to have made an equally good showing, both in the local and general symptoms, his cough is very much better indeed, and we have but few bacilli as compared with four weeks ago. Two other cases of this class are also improving, both locally and generally, and are within reach for your examination and comparison of records.

The rest are three ladies, who beg to be excused, one of them a sister of the case already mentioned; she has an organic heart lesion, but I have not observed any special disturbance of the circulation under the lymph; she has had an intercurrent attack of influenza, during which she lost a little in weight; previously she had been gaining, and her weight is now again increasing. Her local symptoms have also improved, but owing to the heart lesion, I have increased the doses with still more caution, and have reached only 8 milligr., to which she reacted locally three days ago, but not to-day.

Another lady patient with excavation of entire upper lobe did not react up to 2½ milligr., when quite unexpectedly upon increase of ½ milligr. a general reaction to 104° F., and intense local reaction followed. The temperature did not again reach the normal for four days, and now she still reacts locally to 2½ milligr., moist sounds are now absent except when local reactions occur, but over the cavity we now have dry creaking and rubbing sounds, which were not present on admission, nor for months before, while she was under my care. The sputum increased enormously after that severe reaction, and the number of bacilli and the elastic tissue were also much increased; now these symptoms are gradually subsiding. She lost ten pounds in weight in the first three weeks and has gained two pounds since. Her larynx, where reactions occurred in the early part of the treatment, is much better. Still another lady patient, making the eighth case of this class, is following a very satisfactory course.

Of the eight cases belonging to the third class, I desire to show you this gentleman, who was so much reduced when he arrived that we withheld the remedy for three or four weeks, during which we have been able to control his fever so that he now seldom reaches over 100° F., his appetite (with a gain of flesh of three pounds) also became better under the management.

For a month he has now been receiving the lymph, has arrived at 3 milligr., his general improvement continues, he having gained four and a half additional pounds. As attributable to the lymph I may mention less cough and expectoration, especially at night, during which he now has uninterrupted sleep. The microscopical changes are also favorable. Locally I can show you nothing of any importance, and perhaps the time and quantity of lymph used is not enough to produce any marked changes.

Two other cases, with extensive involvement of the larynx, have before and since taking the lymph shown much elevation of temperature with active local processes in the lungs. The lymph in these cases was discontinued, although it could not be said to have exerted an unfavorable influence, the doses were very small. They are now upon other methods of management, and the lymph is not to be used again until they are practically free from

fever. In the larynx we now use lactic-acid application; in one case considerable reduction of swelling occurred while the lymph was being given.

Two other cases have made fair progress, about like the first case shown you; three ladies are doing very nicely, indeed one who had previously been losing, has gained ten pounds in three weeks, another, also a losing one, has gained several pounds, and a third one is certainly holding her own.

This leaves another case, that of a gentleman, in which I cannot say that any change has occurred, one way or other; he had been losing before he came, and now holds his own, but beyond some general improvement, the lungs are the same, although distinct local reactions have occurred. He has only been treated for two weeks.

In one case of the first class the lymph was employed for its diagnostic value, the patient could furnish no expectoration; local and general reaction occurred from 2½ milligr., the temperature reaching 102° F. Sputum was present next day, and bacilli were found for the first time in great numbers.

Mr. President and Gentlemen, you have now been able to see what has been accomplished in these cases; some of the results are indeed very striking, and if I desired cheap notoriety I could undoubtedly gain it by discharging several of these patients as cured. But these cases would be worse for it in the end, and the reported cures in this country strike me as absurd and entirely premature. I am equally doubtful of reports of clearing up of large or small areas of tubercular infiltration, so that the percussion note became normal, and the bronchial breathing again vesicular and normal. How such changes should follow the employment of any means, no matter how specific their action might be, is to me incomprehensible. The lesions which might have been so changed can never have been tubercular, and the most I can believe is, that they were pneumonic processes or had been simulated by collapsed lung portions; but even then I am at a loss to understand how the lymph removed one or the other.

Disappearance of râles may again allow us to hear the previously masked vesicular respiration, and I have seen pneumonic processes clear up, but have never been able to procure normal conditions of the respiratory and percussion phenomena in tubercular deposits under any mode of treatment. The connective-tissue changes which occur in the process of a cure, must ever remain as the evidence of the previous disease, and our patients are none the less cured when these conditions have become permanent.

I am, therefore, for the present, unwilling to speak of absolute cures from the use of the lymph, which in the short time cannot be expected, and I have no case in which I can demonstrate that the tubercular tissue has been replaced by new lung.

The local improvements consist in clearing up of râles and ronchi to their entire disappearance; of connective-tissue change taking the place of the tubercular; in the absence of the râles from mucus and pus; and in freer and less obstructed respiration.

Before we had the new remedy, I accomplished all these things in this institution, and in looking over my records of a year ago, I find that on March 1, 1890, there was not a single case in this house which was not improving.

To those laboring outside of institutions, such results are perhaps more surprising, but I am satisfied that without the general management, painstaking carrying out of the climatic treatment, the regulation of diet and avoidance of over-exertion, our showing would have been less favorable.

Neither is the general improvement of these patients a new feature in my experience. There is, therefore, nothing characteristic by which we could see the effect of the remedy, unless it is the effect upon the expectoration. Changes for the better, at least in some cases, produced so promptly, even after one or two injections, I have never seen before, and I have prepared many thousands of slides for microscopical examinations. The rapid diminution in quantity is also striking, and with it the cough is reduced or entirely removed, but that occurred only in a minority.

I must, however, state that while I have seen all the local and general improvement in my previous experience, that under the lymph they appeared more promptly and more uniformly, in other words I feel that what has been accomplished in from four to ten weeks, would have taken perhaps as many months—but such matters are difficult to estimate.

My conclusions may be formulated as follows:

1st.—Professor Koch's remedy has a specific and selective effect upon tubercular tissues.

2d.—This effect is curative, indifferent, or injurious, depending upon the judicious or indiscriminative use of the remedy in the particular case, and in this respect acts the same as other powerful remedies.

3d.—Local reactions only are to be sought in its application for internal tubercular affections, and no increase of dose is permissible until we are reasonably sure that local reactions have ceased to occur to the previous dose in every part involved. More intense and general reactions and rapid increase of dosage are positively unnecessary, injurious, and may become dangerous.

4th.—That cases with acute softening and breaking down of tubercular deposits, are, as a rule, not suitable cases for the treatment.

5th.—That the therapeutic results from the remedy are such that we must accord it the position of a most valuable aid in the cure of tuberculosis; inasmuch, however, as inflammatory and other nutritive disturbances accompany the disease, which the lymph cannot influence, we are not justified in depending upon Koch's remedy only, but require now, as heretofore, to take advantage of every means at our command.

6th.—That the application of the remedy requires the greatest circumspection, and especially most constant control, not only by observations of pulse, respiration, and temperature, but also with the stethoscope, for observations of local changes in the lungs; and that for its successful use, the patient must be under personal observation of a competent medical practitioner with as much experience as possible.

7th.—That with such precaution the remedy can be administered in all stages of the disease without danger, but that the existing dangers from indiscriminate application are as real in early, as they are in advanced stages.

THE RELIEF OF PELVIC AND ABDOMINAL PAIN BY HOT COLON DOUCHES.

By W. E. FOREST, M.D.,

NEW YORK.

Case I.—Mrs. A——, sixty-five years of age, was attacked suddenly by an excruciating pain in the left loin over the region of the kidney and extending forward and downward toward the groin. She had had similar attacks some months before, for which I had treated her. The attacks were what are usually called "gravel, or kidney colic," and seemed due to the passage of calculi from kidney to bladder, through the ureter. The pain was continuous, but there was no tenderness on pressure. As the pain was intense, the first indication was to give relief, and for this purpose I ordered hot fomentations over the side, and gave one fourth grain of morphine hypodermically. She begged me, after fifteen minutes, to repeat the dose, as the pain did not subside, but I declined to do this. I left some opium suppositories, however, to be used through the night if necessary.

In the morning early the lady's daughter came to my office to report that her mother was getting worse. The injection of morphine had numbed the pain for a time,

but, so soon as the influence of the narcotic wore off, the pain began to manifest itself again, and now it was very bad. The opium suppositories were apparently useless, and the patient wished another injection of morphine. I was engaged at the time and could not well leave. It occurred to me that the ureter, lying as it does immediately behind and in contact with the colon on the left side, might be reached directly by hot applications within the colon. At this point a thin membrane only would interpose between the irritated tube and the local application of heat.

I instructed the patient's daughter to have her mother lie on her left side (partly on the face) with the hips a little elevated. Then the daughter was to very slowly inject into the colon, with a Davidson's syringe, water as hot as could be borne by the hand, a temperature not less than 110° F. I promised to see the patient as soon as I was at liberty, and give morphine if it should be needed. The injection of hot water to be not less than a quart in amount, and to be retained as long as possible. The object of the injection was not to move the bowels but to relieve the pain.

In an hour or so I called to see my patient; found her sleeping quietly. The daughter said that the first injection had been retained about ten minutes. It brought much relief from the pain. When expelled, hardened fæces had come away with it. Another hot injection had then been given, and, while giving it the patient had dropped off into a quiet sleep, the first natural sleep in more than twenty-four hours. That last injection, about one pint in amount, was still retained in the colon.

I left my patient sleeping, with orders that if the pain returned again she was to have another hot colon douche. Saw her in afternoon; there had been no return of the pain, but the side was quite sore. The second injection had never passed from the colon, but there had been a profuse discharge of urine, showing that the water had been absorbed from the colon and passed out of the system through the kidneys. Two more hot rectal, or rather colon, douches were given for the soreness, and the next day my patient was out of bed as active as ever. She passed a quantity of small uric-acid calculi. No stone of any size was seen.

Case II.—J. I——, thirty-two years of age, a commercial traveller; stopping at an hotel. While writing at a desk he was taken with a sudden, sharp pain over the region of the left kidney. The pain was so severe as to make him feel faint, and become sick at the stomach. He went to his room immediately and had been in continuous pain since the attack. I found him writhing on the bed, consumed with a raging thirst, but vomiting everything he drank. He threw up only what he drank, no bile nor mucus with it. He said he had never had a similar attack; was usually in good health. He had been a little dull latterly in body and mind, and he had noticed that the urine had been high cólored and scanty. The pain extended from the left kidney down to the groin. There was no rectal syringe at hand, and the pain was so great he could not wait for one to be procured, so I was compelled to give morphine hypodermically.

His brother had been sent for, and came while I was present. I explained the situation, and asked to be sent for if the pain returned. Four hours later I was summoned again. The attendant said that after the morphine injection the pain had been less severe for an hour or two, but the last two hours it had steadily increased, and had now become unbearable. The patient said that it was now as bad as when I first saw him; vomiting continued.

I prepared the hot colon injection, had my patient lie partly on his left side and face, and instructed the brother how to administer the douche. The fluid was pumped into the colon very slowly and retained. In a few minutes the groans ceased, and by the time a pint and a half had entered the colon the patient was quietly sleeping. In this case also the water was retained in the colon and absorbed into the system. In the evening, after another douche, my patient took the train for his home in Philadelphia.

Case III.—A lady, unmarried, aged thirty-one, an artist by profession; nervous temperament, subject to fainting attacks. I saw the case first while she was suffering from what she called "ovarian neuralgia." I obtained the following history: For the last two years she had been suffering with pain over the region of the left ovary at the time of the menstrual period; the pain was worse just before the flow, but continued during and after it. This trouble had grown steadily worse. During the last six months it had been especially bad, and for two weeks in each month she suffered excruciating pain in the left side in front, and radiating down the front of the thigh. This pain was paroxysmal in character and periodical. For instance, it would come on at about 1 P.M. and grow steadily worse until evening, when she would be almost beside herself with pain. By seven o'clock the pain would begin to die out; then a period of comparative ease until one o'clock in the morning, when the pain would return with all its force and last until daylight. There was marked tenderness over the left ovary during the time that the pain was present. This suffering had continued for a week, and would last for a week more at least. She was conscious of some pain all the time throughout the whole month.

She had been under the care of a physician, but he had not been able to give her relief except by the use of morphine; this drug prostrated her so that she could not use it. She had taken antipyrine and quinine with little or no effect. Had taken three doses of antipyrine that afternoon, together with two little pellets of something she did not know the name of, but it was said to be a specific for neuralgic pains. None of these remedies had relieved her in the least: would I do something to help her, as her doctor was out of town, and she could not stand the pain much longer?

I explained that so far as drugs went I had nothing to suggest different from what she had already tried. Morphine she could not take, and the others had failed. I suggested that she might try the hot colon douches; while I had never tried it in just such a case as hers, it seemed as if they might relieve the pain. At least it was the "forlorn hope," as there was no other remedy that I could suggest. The sufferer gladly consented to try this treatment, and her mother was instructed in the method of using it. The method, in brief, was to have the patient lie partly on the left side and face, left arm behind the back, and hips elevated on a pillow, the water to be forced in very slowly and retained as long as possible.

The mother carried out my instructions carefully, with the result that in fifteen minutes the pain had mostly subsided. After resting for half an hour the patient dressed and went to dinner, and ate quite heartily. This was contrary to orders. A few minutes after dinner she had a fainting attack or collapse that alarmed her mother very much. Whether this was due to the antipyrine taken during the afternoon, or to the colon flushing followed by the exertion of dressing, I cannot say. To avoid any trouble of this kind again, I ordered a stimulant before using the flushing, and rest in bed for an hour or two after it.

While the pain had been relieved for the time being, it was not certain that the relief was due to the hot flushing, as the drugs taken during the day might have at last taken effect. Again, the pain usually grew less in the evening, though not so rapidly and completely as it had after the douche.

However, the attack was due again at 1 A.M., when there would be an opportunity to test the new treatment. I ordered a hot flushing to be taken that night a half hour before the pain was due, and again the next day at noon, before the afternoon pain was expected. If the pain became severe the flushing was to be repeated during the attack. The following day I learned that the

flushing given at midnight almost checked the expected attack. There was a slight manifestation of the pain, but not enough to prevent sleep. There was no further pain after this. The patient took a hot flushing every night for the effect on the ovary, but was soon about the house, though her strength returned very slowly. She stated that her system seemed shattered by her sufferings. There was still soreness on the left side in the ovarian region; but day by day this became better, in spite of the fact that she went to her studio and did some work.

Ten days after the cessation of the menstrual flow she came to my office with her mother. It was important to know, on account of a proposed journey, whether there was any local trouble in the ovarian region to account for these attacks, and to see what the hopes of a permanent cure might be. On examination I found a hard, round swelling in the left broad ligament, close up to the uterus. This was exquisitely tender to the touch, not movable, and evidently, partly, at least, inflammatory in character. It was so tender that I could not determine at that time how much the ovary was involved. As my patient was going out of town, I could only suggest a blister over the region of the trouble and the use of the hot colon douche each night. Her great fear was the return of the pain at the next menstrual period.

On her return to the city, some weeks later, I learned that she had put on the blister and had remained quiet during the rest of a month. She had taken the hot colon douche every night. The menstrual flow had come on at the proper time without pain; had continued free from pain for three days; on the third day she had had great mental disturbance and trouble, an emotional cyclone, due to family matters, and the next morning the pain returned. It was relieved by the hot rectal douche again, but had tended to return periodically each morning, showing that it was neuralgic in character and was started this time by the mental disturbance.

On examination I found the swelling in the left broad ligament much reduced in size and the tenderness almost gone. I am now treating the case with the daily use of the hot rectal douche, and twice a week the application of galvanism to the swelling in the left ligament—the positive electrode behind the ligament, in the vagina, the negative on the abdomen. In addition she has the foot of her bed elevated eight inches at night, and she is to lie down for an hour in the morning and an hour in the afternoon, with the hips elevated on pillows. This is to relieve pelvic congestion by the influence of gravity, and to stretch the shortened left ligament of the womb.

Since writing the above, a third period has passed almost without pain. The suffering at former periods seems now like a dreadful nightmare.

Case IV.—Mrs. S——, thirty-four years of age. Has had two children, the last eight years ago. She was taken suddenly in the night with great pain in the uterine region. The pain was continuous and accompanied with soreness and tenderness to the touch. It seemed to her like "inflammation of the womb." Her husband used hot applications an hour without the least relief, when the patient remembered that I had once instructed her as to the relief of pain by hot rectal douches. Her husband administered one, and the pain disappeared in fifteen minutes. There was marked soreness over the supra-pubic region for a day or two, but no return of the pain. I did not personally see this case, but obtained the details from the husband of the lady. As near as I could learn, the pain must have originated from the vaginal injection having gone astray, some of the liquid possibly entering the uterus and Fallopian tubes. Every practitioner knows that such accidents often cause serious results.

Case V.—Miss M. F——, thirty years of age; tall, thin, anæmic young woman. Has doctored for many months, but with little or no benefit. Complains of three things, namely, great debility; great pain at her menstrual period, before and during it; and pains in urinating. This latter trouble is a recent one; the pain at her menstrual period she has had for years, but of late it has grown worse. Of course she is of badly constipated habit. For the relief of the pain at the menstrual period, which was about due, I advised the hot rectal douche every night, commencing at once. For anæmia I gave the elix. peptonate of iron.

Three days after the menstrual period she reported again, and stated that she had but very little pain, less than in many months. The hot rectal douche gave relief at once. It had had no bad effect on the flow—had certainly not increased it. She was feeling much stronger than at her last visit, as she had not been prostrated as usual by her period, and the tonic had had an opportunity to strengthen her. She expressed herself as delighted with the effect of the hot colon douche, and said that she should use it during every menstrual period. Has reported since, and there is great improvement. Is free from pains of all kinds, and has a good color in cheeks and lips. Continues the douches.

Case VI.—Woman, aged sixty two. Was taken with a steady pain a little to the right of the epigastric region. She was slightly jaundiced. There was soreness to the touch when deep pressure was made. She vomited occasionally; has had such attacks before. From the history and location of the pain I judged it to be due to a biliary calculus. The patient had been under treatment two days when I saw her. As she was constipated from the narcotics she had taken, I ordered the colon flushed with hot salt water. When this had been done twice, the pain in the epigastric region ceased, and there was no more trouble from the gall-stone. The vomiting ceased and the appetite returned.

The histories of the above cases have been selected out of many others, because they illustrate different types of abdominal and pelvic pain that can be relieved by hot colon douches.

In Cases I. and II. we have the typical kidney colic, one case in an aged female, the other in a young male. Both cases were promptly relieved by the treatment, even when morphine had failed to bring permanent relief. In Case I. the attack was apparently shortened, as I had twice treated her previously for the same condition, and each time it had taken three days before the soreness and pain had ceased. In this last attack it ended much more quickly.

The *rationale* of the treatment in this class of cases is simple. The hot water in the colon comes into nearly direct contact with the irritated and contracted ureter, through which we suppose a calculus to be passing. Now the effect of the heat on living tissues we know to be threefold: 1. It is a sedative to the painful nerves; 2, it relaxes the spasm of muscular tissues; 3, it relieves congestion. Hence our application tended to relax the ureter and allow the stone to pass on to the bladder, and at the same time the pain and congestion were relieved, and inflammation prevented.

A further influence of the treatment is due to the absorption of more or less of the water from the colon. This relieves the thirst without taxing the disturbed stomach, and as the water is eliminated by the kidneys, it washes them and the ureters with a bland liquid. In all these cases I would recommend, after a thorough douching of the colon with the hot water, the injection of a pint of hot water to be retained. This latter will always be accomplished if the patient, after receiving the liquid, lies quietly on the face or side, with the hips on a pillow. Hot mineral waters, saline or lithiated, may be used, if desired, for this latter purpose. The question arises whether pain in the right kidney and ureter will be relieved as well as on the left side? According to my experience, it will, if the douching or flushing be thoroughly done.

I have demonstrated that the hot water can be made to pass throughout the length of the colon to its end on the right side. Here it comes in intimate relation with the right kidney and its accessories.

In Case III.—ovarian neuralgia and inflammation of the broad ligament—we have a similar *rationale* for the relief of pain as in the preceding cases. We need hardly be reminded that the colon is in close contact with the uterus, ligaments, and ovaries. It was once the fashion (after Simon) for the surgeon to insert the hand and forearm into the female rectum for diagnostic purposes. With the hand in the colon the uterus and ovaries are in its grasp, and can be mapped out and examined with the greatest ease, a thin membrane only separating the hand from these organs.

Now the hot water in the colon comes into as direct contact with these organs as did the hand of the surgeon in the same position. In the hot colon flushing the uterus and appendages are immersed, so to speak, in a hot bath.

The effect of heat in relieving congestion, soothing painful nerves, and relaxing spasm, need only be mentioned here. It explains the relief experienced in this case when narcotics and anodynes had failed.

A moment's consideration will show how much more effective a hot colon douche should be in such cases than the usual hot vaginal douche. In the colon douche the hot liquid is applied to, and retained on, nearly all sides of the disturbed organs. In the vaginal douche it is applied intermittingly at one end of the organ. There is as much difference between the effect of the two methods as there is between a warm sponge-bath on the one hand, and a continued hot tub-bath on the other, when the soothing and relaxing effects of a hot bath are desired.

Certainly, in the case related, the pain was relieved by the hot colon douche, when all other measures, such as hot external applications, hot vaginal douches, and the internal use of anodynes, antispasmodics, and even narcotics, had entirely failed.

In Case IV. the patient felt that she had been saved an attack of uterine inflammation by a prompt resort to the hot colon flushing. One thing, at least, was certain, she had been promptly relieved from severe pelvic pain by this treatment.

The next case (V.)—painful menstruation—represents a very large class of sufferers. We would be safe in saying that in this country, among the more intelligent classes, the young women who are free from suffering at the menstrual period are the exception rather than the rule. How great this suffering may be in many cases, only the sufferer and the physician can understand. Not long ago a young married woman told me that for three days at the beginning of each menstrual period she remained day and night in the kneeling posture, as it was only in that position that she could endure the awful agony that was hers each month. If she slept at all during this time it was when, completely exhausted, still kneeling, she rested her head on a pillow in a chair. This is an unusually severe example of a large class of sufferers. Most of these cases, occurring as they do in young unmarried women, will not, nor should they, submit to local treatment by a physican. The best the physician can do in such cases is to prescribe narcotics or antispasmodics, to be used at the time of pain for a temporary effect. These drugs will be used a short time, and then the patient either gives them up, or becomes a victim of the drug itself.

If the physician's advice is not sought through motives of delicacy, the usual home remedy is alcoholic stimulants of some kind, usually hot gin. The quantity drank by some of the sufferers at such times is almost past belief.

The substitute I have to offer in these cases for the narcotics, anodynes, and stimulants, is the hot colon douche. It has absolutely no drawbacks or injurious effects that I have discovered, when properly used, but, on the contrary, has a decidedly tonic and curative influence on the conditions that cause the suffering.

In the majority of these cases there is an undeveloped uterus, often bent upon itself, with sensitive nerves and spasmodically contracted blood-vessels. The influence of the heat upon such conditions is beneficial. Upon the menstrual flow itself, the hot colon douche, used during the flow, has a good effect. If the flow be excessive, the douche lessens it; if scant, it increases it; in short, it regulates the discharge and makes it normal.

In Case VI. the hot colon douche relieved what seemed to be an attack of hepatic colic. This case is mentioned to show that the influence of the colon douche is not confined to the pelvis but extends to the upper part of the abdominal cavity as well. The treatment is particularly appropriate in these cases, as it has long been known that large rectal injections relieve jaundice.

In cases of pelvic pain following a miscarriage, where inflammation seems to threaten, and an immediate recourse to morphine seems indicated, I have found the hot colon douche to relieve the pain almost immediately, and to have a very beneficial effect on the womb and accessories. The hot douche, besides relieving the pain, elevates the organs into place, lessens the congestion, and favors the return of the womb to its natural size. I have the hot colon douche employed daily in these cases.

The foregoing cases are types of the class of cases that I have found benefited by the use of the hot colon douche. I trust that others may give this method of relieving pain in the pelvic and abdominal cavities a fair and impartial trial, so that by an extended series of observations the real merits of the method, if it have any, may be established. There may be cases that will not be relieved by this treatment, but so far it has not failed in my hands. Speaking from my own experience, I feel sure that the hot colon douche will have a quite important position in the therapeutics of the pelvic and abdominal cavities.

It may be well to recapitulate the proper method of using the remedy, for even in so simple a matter as this, there is a right and wrong method. The patient is to lie on the left side, with the left arm behind the back, legs partly drawn up, hips on a pillow or folded blanket, the chest low; in short, in the Sims position. This position allows the patient to administer the injection by the use of the right hand. It is always better, however, to have an attendant administer the injection if possible. If an attendant gives it, the patient might better lie directly on the face with a folded blanket or pillow under the thighs. The water is to be of a temperature not more than 112° F. nor less than 106° F. From a pint to two quarts of the hot liquid should be slowly injected, and retained for a few minutes. If there are fæces in the rectum, as is usually the case, the injection and the fæces will be quickly ejected. Then at once have the patient lie down and repeat the hot injection, using a larger quantity the second time. This will be retained longer and will almost certainly relieve the pain. When this is expelled the patient should lie down again, and about a pint of hot water should be injected; this will be retained if the patient lies quiet, and it will be discharged from the system through the kidneys. If the patient is at all weak, it is wise to administer a stimulant before giving the injections.

In another article will be given the results of experiments to determine the effect on healthy and diseased kidneys of hot colon douches retained and absorbed.

39½ Washington Square.

The Influenza in Austria.—The Austrian Minister of the Interior has published a report of the epidemic of influenza in that country during 1889 and 1890. The disease appeared in November, 1889, and continued until the end of January, or in some places even through March, 1890. The total number of persons applying for medical relief during that time was 930,478, but there were many other cases which were not seen by any physician, and consequently were not reported to the authorities. In Vienna the number of reported cases was 42,794, and of deaths, 338. The total number of deaths in Austria directly attributable to the influenza was 2,823.

THE THEORETICALLY IDEAL REMEDY FOR PULMONARY PHTHISIS.

By WILLIAM MOOR, M.D.,

NEW YORK.

LITTLE attention, if any at all, has been paid on this side of the Atlantic to Professor Liebreich's new plan of treating tuberculosis. Our physicians, who so readily resorted to a therapeutical agent the composition of which was a mystery to them—I refer to the famous "lymph"—did not even make an attempt to give another remedy, so easily obtainable and comparatively harmless, a trial. At the séance of the Berliner medicinische Gesellschaft, held on February 25, 1891, Professor Oscar Liebreich, the eminent scientist to whom, among various pharmacological discoveries, we owe chloral hydrate, laid before the present members of this society the results of the researches and experiments he had made with respect to cantharidin. Though his investigations were not yet completed, he did not want to hold in suspense any longer those that were informed about certain experiments upon which they had founded great hopes. On experimenting upon animals, he had found that the cause of their death from acute cantharidin poisoning was dyspnœa, due to a slight transudation of blood-serum from the lung capillaries. There occurred no change in the blood-pressure and in the action of the heart, as was shown by the kymograph. Liebreich, therefore, concluded that cantharidin, if injected hypodermically, gives rise to a peculiar modification of the lung capillaries, the nature of which we cannot explain, causing an exudation of serum. It is also to be expected that capillaries, which are pathologically irritated, would yield more quickly to the influence of cantharidin than normal capillaries. Professor Liebreich, on the basis of such observations and reasoning, commenced his clinical experiments upon patients affected with laryngeal and pulmonary phthisis. Simultaneously, a number of tuberculous patients were treated with injections of cantharidin, by Professor B. Fränkel, Dr. Landgraf, and Dr. Heymann. Liebreich's supposition was that the exuded serum may contribute to the nourishment of the diseased tissues, also that the serum may exert its bactericidal influence upon the pathogenic microorganisms. The results obtained by this new method of treatment were remarkable.

I desire now to bring forward my own views as to the action of cantharidin. I consider cantharidin to be the ideal remedy for pulmonary phthisis; but from a standpoint which is entirely different from Professor Liebreich's explanation of the "modus curandi" of cantharidin. Presently I shall leave aside its possible effect upon tubercular ulcers of the larynx, but shall consider chiefly its therapeutical relation to pulmonary consumption.

It is a well-known fact that pulmonary phthisis seldom follows an attack of acute lobar pneumonia, and that lobar pneumonia rarely supervenes upon pulmonary phthisis. In fact, I do not consider it sufficiently proved that the pneumonia observed in phthisical patients is really the genuine pneumonia, the pneumococcus pneumonia. It seems to me much more probable that these cases are of the lobular, catarrhal type, or else that the signs attributed to lobar pneumonia are due to a temporary caseous infiltration with subsequent resorption of the products of infiltration. Only recently,[1] during a discussion on "tuberculin," Virchow stated that occasionally a genuine pneumonia may attack a phthisical subject, but this is an occurrence of extraordinary rarity. If a real pneumococcus pneumonia is apt to invade a phthisical lung, it would be expected that we should find in a corresponding frequency, at the autopsies of persons deceased from acute lobar pneumonia, tuberculous changes in the lungs. In studying various statistics I have met with but very few instances of tubercular lesions having been found in the lungs of subjects that had died from lobar pneumonia. At the Roosevelt Hospital, for instance, during the years 1885, 1886, and 1887, there are reported seventy-seven deaths from lobar pneumonia; phthisis is mentioned as a complication in but one case. During the same period, out of one hundred and eight subjects deceased from pulmonary phthisis, but one is reported as having had as a complication lobar pneumonia. Dr. Chelmonsky,[1] of Warsaw, on studying the autopsy reports in the "prosectorium" of the I. therapeutical clinic of that city, did not find a single case of a person deceased from acute lobar pneumonia, in whom were noticed tuberculous changes in the lungs.

There evidently exists a decided antagonism between the pneumococcus and the bacillus tuberculosis. It is considered an established fact that certain species of bacteria are antagonistic to other species of germs. According to my own idea, such an antagonism can be of a twofold character: it may be either chemical or dynamical. Some bacteria are antagonistic to each other outside of the animal organism on account of their metabolism products, whereas other bacteria prevent the growth and multiplication of other species only within the human or animal organism. This latter phenomenon I call "dynamic antagonism of bacteria" in distinction to the chemical antagonism, which exists outside the body and depends on the ptomaïnes and other products of metabolism. Applying this to our subject proper, we may say that the pneumococcus and the bacillus tuberculosis are dynamic antagonists. Which is the chief dynamical characteristic of a pneumococcus invasion of the lungs? Is it not the transudation of blood-serum from the pulmonary capillaries? Therefore, if we can find some mineral, vegetable, or animal substance which is capable of producing a transudation of serum from the lung capillaries, such a substance could be considered a dynamical substitute of the pneumococcus.

I think, Liebreich has found such a substance in cantharidin, and has therefore given us the theoretically ideal remedy for pulmonary consumption. The practical results so far obtained with this therapeutical agent seem to confirm its theoretical importance. It is strongly to be wished that those of our physicians who have ample opportunity to carry out the clinical experiments with respect to the therapeutic effects of cantharidin, should do so without delay. Its use—as compared to Koch's "lymph"—is harmless.

The solution for injection is prepared in the following manner:

Take 0.20 gramme of cantharidin and 0.40 gramme of hydrate of potassium, or 0.30 gramme of hydrate of sodium. Weigh exactly and add 20 ccm. of distilled water. Warm in a water bath until a clear solution is obtained. While the warmth is maintained, add gradually distilled water until the solution becomes cold, then add cold distilled water until the whole amounts to exactly one litre.

One cubic centimetre of this solution contains 0.0002 gramme of cantharidin. The normal dose for injection is 0.0001 or 0.0002 gramme, but it is probably better to commence with ½ decimilligramme, *i.e.*, ½ of a cubic centimetre of the solution. The maximum dose is 0.0004 gramme. The injections should not be made daily, but alternately on every other day. Renal disease is a contra-indication to this treatment. If an injection is followed by diarrhœa, strangury, or albuminuria, the injections have to be interrupted for some time; from five to ten drops of tincture of opium will promptly allay such symptoms. The most suitable place for injection is between the two shoulder-blades. In injecting, the ordinary rules and precautions are to be observed.

143 WEST FORTY-FIRST STREET.

A CASE OF ANTHRAX — EXCISION OF INFECTED TISSUE—RECOVERY.

By ALEXANDER B. JOHNSON, M.D.,
NEW YORK

WITH A BACTERIOLOGICAL REPORT OF THE CASE.
By G. L. NICHOLAS, M.D.,
NEW YORK.

THE following case seems to the writer worth recording on account of its rarity and of the fact that the diagnosis was proven bacteriologically. The clinical history is as follows:

O. B— , aged forty-one, a wool-sorter by occupation, employed in a large carpet manufactory in New York City, presented himself at the Out-patient Department of Roosevelt Hospital on January 4, 1890. He stated that during the night of January 1st he had been awakened by a stinging pain in his right cheek. In the morning he observed a painful, tender, swollen, red spot in the middle of his cheek, and believed that he had been bitten by some insect, presumably by a black spider. The pain and swelling continued and slowly increased, without any constitutional disturbance, until January 4th, when he came to the hospital for treatment.

Examination showed a black, slightly depressed scab, about half an inch in diameter, at the level, and one and one-half inch in front, of the lobule of the right ear. This scab was surrounded by an areola of small vesicles which were filled with pink serum, and these by an indurated red margin of inflamed skin about half an inch in width. The entire right side of the face was swollen moderately, and the swelling extended downward for some distance on the neck. The patient expressed himself as feeling perfectly well, except for the pain and discomfort in his face, which were not very great.

Inquiry elicited the fact that he had recently been occupied in handling wool imported from Spain. The appearance of the sore led to a suspicion of anthrax, and a portion of the scab, together with some drops of bloody, turbid serum from beneath it, and a little of the necrotic tissue which formed the base of the ulcer were scraped away with a sterilized sharp spoon, introduced into a sterilized test-tube, and sent to the Pathological Laboratory of the College of Physicians and Surgeons for examination. A report was made in a few minutes that rod-shaped bacteria, resembling those of anthrax, were to be seen in the specimens examined. The patient's face was cleaned and disinfected, in the ordinary manner, with soap and water, turpentine, alcohol, ether, and bichloride solution (1 to 1000). A solution of cocaine was introduced into the skin surrounding the pustule, which was then cut out, including a border of about half an inch of apparently healthy tissue. The raw surface was repeatedly swabbed with a solution of zinc chloride, forty grains to one ounce, and the edges were partly drawn together by means of two catgut sutures. After twenty four hours the swelling had for the most part disappeared from the patient's face. After the separation of the superficial sloughs, caused by the zinc chloride, the wound healed rapidly and the patient had no further trouble.

Biological and Morphological Analysis of Dr. Johnson's Case of Anthrax.—Cover-glass preparations made directly from the ulcer showed, among others, bacteria with all the morphological characters of the bacillus anthracis. From discharge of ulcer sowings were made upon an agar plate. In the course of four days this plate developed forty two colonies, presenting the appearances characteristic of the anthrax bacillus. Sections of the original ulcers, stained by Gram's method, showed very great numbers of bacilli. They were sharply confined to the immediate neighborhood of the ulcer, affecting its margin rather than centre. Two white mice, inoculated with the discharge and fragments of scrapings from the ulcer, died in thirty-six hours. The autopsies showed all the lesions characteristic of anthrax. Cover-glass preparations, from the blood in the heart, liver, and spleen of these mice showed very many bacilli similar to those obtained directly from the ulcer, and occurring in sections of ulcer. Gelatine plates from the blood of the liver, spleen, and heart of the mice rapidly developed innumerable colonies, having the characters belonging to anthrax. Pure cultures from these colonies grew in a characteristic way, and the bacilli presented all the morphological characters of anthrax bacilli.

A third mouse, inoculated from this last set of cultures, died in thirty-six hours. The autopsy showed the lesions of anthrax, and cover-glasses from the blood of the liver, spleen, and heart presented bacilli, the same as in the preceding case, while the cultures grew as before.

Diagnosis—anthrax.

INJECTIONS IN SYPHILIS, AND A HANDY METHOD FOR CURING SYPHILITIC PALMAR PSORIASIS.

By J. HUNTER WELLS, M.D.,
PORTLAND, ORE.

HAVING noticed with interest an editorial a few weeks ago on the injection treatment of syphilis, and knowing that it is not yet a favorite method in this country, I am led to report a case which has come under my observation.

It presented a fairly characteristic syphilitic ulcer of the tongue, about the size of a fifty-cent piece, though irregular in outline. The appearance was quite serious, a suspicion of cancer being entertained, but the edges and base were of a specific type, though no specific history at all could be obtained. The pharynx and uvula, with a portion of the soft palate, showed ulcerative change, leaving little doubt as to the condition. As the patient could hardly talk, and could only take liquid and soft diet, and was rapidly losing flesh, it became necessary to do something active, so I put him under the injection treatment, which I learned from Professor Hebra, of Vienna. The solution I used was:

℞.	Hydrarg. bichlorid.	grs. xv.
	Sodium chlorid	grs. xc.
	Aqua dest.	ʒ iv.

Of this I injected deep into the buttock, fifteen minims, once a day. At the end of the tenth day a decided improvement was manifest, which continued up to the twentieth injection, the last ones being given every few days instead of every day, until all traces but a cicatrix with raised edges, were gone.

Several weeks after the patient again presented himself as bad as ever. He had gone back to his inveterate smoking, and had been doing nothing in the way of medication. I gave about thirty more injections, and then stopped them and gave iodide of potassium, which he took for some time, and is now apparently nearly cured of the trouble, two months having elapsed with no recurrence of symptoms. It might be said that iodide of potassium given at first would have acted equally well, but I am inclined to doubt it, for it is well known that potassium, in specific affections, acts much better after mercury has been administered.

A few other cases of primary syphilis, in which the injections were used, presented no unusual features. One, however, had palmar psoriasis, which was treated locally by fumigation with calomel, to which I wish to call special attention, it being, so far as I can learn, an original method with Dr. G. M. Wells, of this city, and entirely satisfactory in quickly curing every case in which it was tried.

A hole large enough to admit the hand is cut in an ordinary hat-box, a half to one drachm of calomel is put underneath on a tripod, and a spirit-lamp produces the fumes, which form a deposit on the hand.

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

New York, May 23, 1891.

THE MEDICAL PROFESSION IN JAPAN.

A RECENT number of the *Sei-I-Kwai Medical Journal* contains an interesting article on the present position of medical practitioners in Japan, in which we see that our confrères in those distant islands have not been behind their fellow-countrymen in the earnest efforts which all have been making to bring their country into the first rank among the civilized nations of the earth.

The writer of the article to which we refer divides the medical profession in Japan into four classes, viz., 1. *Kanpô-ka*, or Chinese school; 2. *Kan-ran settû-ka*, or China-Dutch school; 3. *Seiyo-ka*, or European school; and 4, *Senmon-ka*, or specialists.

Those included under the first head, the Chinese physicians, are the most numerous, comprising perhaps one-half of the entire number of practitioners in the empire, but their number is rapidly decreasing since the new law in regard to medical licenses prevents any accession to their ranks. Most of them are of the older generation, few being under fifty years of age. They are absolutely guiltless of any medical learning, all the knowledge that they possess having been gathered by the perusal of the absurd medical treatises of the Chinese. Their medicines consist in certain herbs and the bark and roots of various plants, which are always given in the form of decoction; they occasionally also employ a few mineral preparations.

In the so-called China-Dutch school there are now about ten thousand members, or half as many as in the Chinese school. They gathered most of their knowledge in the same way as those of the first class mentioned, but they supplemented it by the study of some old works on medicine which had been imperfectly translated from the Dutch into Japanese. They treat disease much in the same way as the Chinese practitioners, but also use drugs of the European Pharmacopœias, such as opium, calomel, iron, soda, asafœtida, aloes, santonine, etc. They are, as a class, liberal in their views, and the progress made by European medicine in Japan is due in no small measure to the encouragement offered by these practitioners, who, though unable to acquire the new knowledge themselves, recognized its advantages and did what they could to promote its spread among those of the younger generation. Some, indeed, did not shrink from the task of learning what was now presented to them by Western physicians; they studied the new science, adopted the new practice, and are now among the most learned and respected of the modern school in Japan.

The number of physicians who belong to the European school is about five thousand, but this number is constantly increasing in proportion as that of the former classes is diminishing. The practitioners included under this head are those who have been educated either abroad or in their native schools which are conducted under government inspection and are provided with thoroughly competent instructors. The chairs in the university and in the various medical colleges are occupied by the members of this class, and all the important positions, both public and private, including those in the medical departments of the army and navy, are held by them.

In the fourth class are the specialists. Some of these are competent physicians, educated in the new school, and practising a legitimate specialty, such as diseases of the eye, dentistry, obstetrics, or the like, but the greater number is made up of ignorant quacks, such as flourished in former days before scientific medicine had gained a foothold in Japan.

The medical practitioners of the new school in Japan at the present day are a superior class of men; they are intelligent, energetic, and enthusiastic; they regard themselves in the light of missionaries, and shrink from no task which they believe will forward the progress of rational medicine in their country. They have established medical societies and medical journals, and have even created a national medical associaton, the first meeting of which was held in Tokio in April of last year. They have passed from the stage of pupillage and now control themselves the course of medicine in their country, being no longer dependent upon foreigners either in their hospitals or in their university chairs. Even *Sei-I-Kwai Medical Journal*, to which we are indebted for most of the information here presented, has no longer an American editor, its English department being now conducted (and most creditably conducted, we may add) entirely by native writers. In contemplating the admirable progress made in this most interesting country, we may becomingly indulge in a little modest self-complacency, since American medicine has had no insignificant part in promoting it.

CURE BY MIRACLE.

THE age of miracles was popularly supposed to have terminated some few centuries ago, but such is not the case, at least so far as St. Louis is concerned. The following is a brief report of one of the latest and best from that city: "For five years Sister Mary Philomena had suffered from an abscess that threatened permanent injury to the brain. Partial blindness resulted. On Tuesday, Sister Baptista visited the sick nun, and offered up a Novena in private prayer. She also gave her a relic. In a paroxysm of pain, Wednesday night, Sister Philomena swallowed the relic. When she awoke, she felt a strange pricking above her eye. Lifting her hand to the spot she felt a needle, which she grasped and pulled out, and, transfixed on its point, was the relic that the sister swallowed. The truth of the marvellous miracle," the account goes on to say, "is vouched for by Dr. Alt and the Mother-Superior." We confess ourselves glad that the transfixed relic part of the story has been vouched for, else 'twere hard to

credit. Should this fall under the eye of Dr. Alt, we sincerely hope he will send further details of the relic's progress from the stomach to the eye. That the needle should have effected its exit through the orbit is not so wonderful, since we are told that it is easier for a needle to pass through the eye than it is for a rich man. The probable interpretation of this being, that if a lady gets a rich man in her eye it is harder for him to escape than it would be for a needle similarly situated. Dr. Oliver W. Holmes's hypothesis of the total depravity of inanimate objects can alone account for the perversity of the needle in remaining in the lady's eye until it was furnished with a relic to transfix. Many instances have been placed on record of particles of glass passing through the eye, but investigation has almost always brought out the history of a man with an eye-glass, or a man with a glass eye, as party of the first part, and a man with a fist, and possessing a knowledge of its use, as party of the second. Miracles are always interesting, and if Dr. Alt knows of other instances equal to the one related, it is to be hoped he will not withhold them.

THE RARITY OF VENEREAL DISEASES AMONG THE LABORING CLASSES OF PARIS.

Parisians, whether of the upper or lower walks, have never been celebrated for the purity of their lives, and it is a common impression, fostered, if not created, by writers of the Zola type, that nowhere is sexual virtue less esteemed than in the French capital. It is possible, however, that French novelists have been less realistic than they would lead us to believe, and that there is really no more vice there than in any other city. Such a view is strengthened by some statistics recently adduced by Dr. L. Fiaux concerning the prevalence of venereal disease among the working population of Paris. In his capacity of surgeon to a railroad company he was called upon to examine a great many laborers and artisans who had applied for employment on the road. He gives the results of these examinations, as regards the existence of venereal disease, in the *Gazette des Hôpitaux*, November 18, 1891. Between September 1, 1888, and December 31, 1890, he examined 3,240 men in the prime of life, two-thirds of them being unmarried and aged from twenty to forty years, the other third being married and aged from twenty-five upward. Out of the entire number Dr. Fiaux found but five suffering from gonorrhœa and from simple ulcer of the penis accompanied with a suppurating bubo in the groin. Not one of those examined was syphilitic or had apparently ever been so.

This is indeed a remarkable showing, but we are inclined to believe that it is an exceptional one, and that a more extended series of examinations would show that the proportion of venereal diseases is far higher than the author would have us imagine. It would be interesting to compare these results with those of similar examinations in other cities and countries.

A NEW SUBSTITUTE FOR QUININE.

We have become so accustomed to read every week or so of a new coal-tar derivative rival of quinine that it is really refreshing to hear of a vegetable substitute for this drug, and one is predisposed in its favor for the simple reason that it is not the product of some chemical laboratory.

The name of this new remedy—new, that is, to the Western World—is halviva, a substance prepared from kreat, an East Indian plant. Dr. G. Yeates Hunter, formerly Brigade Surgeon in the Bombay Army, describes it in the *British Medical Journal* of March 7, 1891, and says that it has long been in use in India as a remedy for malaria, and as a tonic and restorative. It possesses all the antimalarial properties of quinine, without apparently any of its disadvantages. It produces none of the head symptoms or nervous irritability so often seen after the long-continued use of quinine, while its therapeutic action is much more reliable. Again, kreat may be taken with great advantage, Dr. Hunter maintains, as a prophylactic, whilst the injudicious use of quinine for that purpose in malarial countries has resulted, in many instances, in marked deterioration of health. As a tonic, the writer declares, halviva is unrivalled, being a pure, clean bitter, without astringency, and acting as a gentle laxative by increasing the secretion of bile. It is of great service in indigestion accompanied by constipation, and is also useful in gouty dyspepsia.

Dr. Hunter does not speak of its possessing any antipyretic properties, and it is probable that he refers to its use in the chronic forms of malarial poisoning rather than as a remedy for acute paludal fevers. So it would appear that we are not, after all, to be freed from the tyranny of the chemical laboratory, and phenylacetamide, dimethyloxychinizin, para acet-phenetidin, tetrahydroparamethyloxychinoline (or tetrahydroparachinanisol), and other such like simples must yet be prescribed by the fever-fighter who puts not his faith in cold water.

THE DANGER FROM ARSENIC.

The condition of our esteemed and interesting colleagues of Massachusetts is again exciting anxiety and alarm. Having passed safely through disquieting exacerbations of homœopathy, mind-cure, Ibsenism, and psychical research, the profession has been brought up sharply with an attack of arseniophobia.

The deaths in Massachusetts from suicide by arsenic are on an alarming increase. The mortality from arsenic in 1887 was 8.8 per 10,000, or nearly 0.1 per cent. of the total mortality. One physician, Dr. Putnam, reports twenty-six cases of poisoning from wall-paper alone, and a twenty-seventh case of a lady who was poisoned from the covering of an easy chair. Danger lurks in all the comforts of the Massachusetts home. Dr. Folsom has seen a patient poisoned by a curtain, and Dr. C. P. Putnam found that the infants of the Infant Hospital were being poisoned by the blue dress of the trained nurse. And what, we would ask, is the good of living if Massachusetts is to shatter our faith in that modern idol, the trained nurse, and show that, instead of being an angel of comfort and light, she may possibly be only an arsenious compound.

Professor Lyon, of Harvard College, also tells a terrible tale. He is one of five Harvard professors all of whom had had cases of arsenical poisoning in their families. He had himself seen forty cases. It appears to

us that the professor has missed his opportunity; he should have reported the epidemic and showed its contagious character, for the evidence seems to accumulate in favor of the view that in Boston mural arsenic poisoning is an infectious disease.

Dr. C. P. Worcester has examined fifty specimens of urine from ordinary dispensary patients and found arsenic in nearly one-half the cases. This again shows the extraordinary prevalence of latent germs. In fact there seems to be an appalling possibility that Massachusetts is being systematically poisoned by an inoculable, malignantly infective, and extremely prevalent form of arsenical poisoning. We rejoice to learn that the Legislature and State Board of Health are at work upon the matter.

PHYSIOLOGICAL EXPERIMENTS ON THE EFFECT OF ALCOHOL.

It has been well established in late years that under certain circumstances the continued use of alcohol produces a form of inflammation of the nerves known as multiple neuritis, or clinically, as alcoholic paralysis. These cases are rare and often occur in those whose indulgence in alcohol has not been excessive, so that it has seemed as if some element besides alcohol alone was necessary to cause the nervous disorder. Experiments with alcohol upon the lower animals have not heretofore shown that its continued use produces any such condition as multiple neuritis in man.

In a recent essay, however, by Dr. P. F. Spaink, of Baarn, Holland, to which was awarded the Mason Prize, some facts are given which seem to show that alcohol does have a directly degenerating influence upon the peripheral nerves. Only an abstract of Dr. Spaink's work has as yet appeared (*Journal of Inebriety*), and many details are lacking. But we learn that Dr. Spaink fed several series of rabbits with pure alcohol, giving them from 2.3 to 8 cubic centimetres daily(ʒ ss. to ℥ ss.). The animals were finally killed and the peripheral nerves examined microscopically, control animals being used. In the great majority of cases degenerative changes were noted. They consisted essentially in a splitting or fissuring of the nerve, with the appearance of elongated, usually large, collections of myeline, thickened or thinned parts of nerve fibres, myeline drops, or simply neurilemma sheaths. Very rarely could any increase of nuclei be observed.

Besides this a large number of specimens showed, in addition to the above-described degeneration, a further peculiarity. This was a twisting or looping, after a corkscrew fashion, of the axis cylinders. These corkscrews recurred at varying distances on the same or neighboring fibres. At these twisted spots the axis cylinders appeared thicker, broader, and more diffuse than when their course was direct. Sometimes in badly-stained preparations these corkscrews were all that could be seen of the axis cylinder.

Since a splitting of the nerve fibres and corkscrewing of axis cylinders are changes unknown to human nerves in alcoholic neuritis, the correctness of Dr. Spaink's findings is likely to be questioned.

A corkscrew appearance of the nerves in alcoholism is, however, very suggestive, since that interesting and useful spiral instrument plays so large a part etiologically in the disease. Is it possible that Dr. Spaink is a grim joker who has been trifling with the pundits of the American Association for the Study and Cure of Inebriety? One must not forget Dr. Dujardin-Beaumetz and the pigs to which he gave alcohol for two and a half years without causing serious structural changes anywhere. There were no corkscrews in the pigs.

News of the Week.

The Managers of the New York Cancer Hospital gave a musicale at the hospital, Eighth Avenue and 106th Street, on Saturday, May 16th, to commemorate the completion of the Astor Pavilion and Cullum Chapel. The following artists kindly volunteered their services: Miss Stoddard, Miss Lawler, Mr. Rieger, Mr. Hilliard, Mrs. Le Moyne, and others. The new pavilion is for male patients, and is completely equipped, but depends for its maintenance on voluntary contributions.

The New York Skin and Cancer Hospital opened a new pavilion at Fordham Heights last week. The occasion was taken to celebrate the work of the hospital during the past nine years. Speeches were made by the President and by the Secretary of the Medical Board, Dr. St. J. Roosa, and Rev. R. S. MacArthur.

Seventeen Members of the Canadian House of Parliament are physicians.

Concerning State Medical Examinations for New York.—The amendment to the law passed in 1890, creating a Board of Medical Examiners, provides that those who claim exemption from the State Examinations shall file certificates of his or her matriculation, before June 5, 1890, within three months of the passage of the amendment. The committee on legislation of the State Society, under instructions from the body that created it, vigorously opposed this amendment, and they now propose to see that no person is exempted without a certificate, and they also propose to look at the documents sent as such. The following is the reply to a note from the committee, addressed to the secretary of the Board of Regents on this subject.

"Regent's Office, Albany, N. Y., May 13, 1891.

"Dr. D. B. St. John Roosa,

"*Chairman Committee on Legislation, New York City.*

"Dear Sir: Replying to your request of May 11th, I beg to say that the Committee on Legislation of the State Medical Society will always be given every facility to examine all records and papers pertaining to the licensing of physicians in this State. As I understand it, these matters are of public record, and any citizen has a right to see them. Beyond that, the sympathies of this office are warmly with your committee and all others who are trying to free our great State from the reproach of practitioners who are deficient in general and medical education. It will therefore give us pleasure to offer you any reasonable facility in exercising the watchful care delegated to you by the State society.

"Very truly yours,

"Melvil Dewey."

Phenocollum Hydrochlorate is the name of a new antipyretic, allied to phenacetin, and given in doses of 7 to 15 grains.

Thyroid Grafting in Myxœdema.—Dr. W. J. Collins, of the London Temperance Hospital, has transplanted the whole thyroid gland from a sheep into the submammary region of a woman suffering from myxœdema. The organ, which weighed from six to eight ounces, must have become quite "vitalized," as there was no suppuration, and the wound healed by first intention. It is too early to speak of any marked result; but, in the four weeks that have elapsed since the operation, the patient's general condition and appearance are stated to have improved.

The Fifty-ninth Annual Meeting of the British Medical Association will be held at Bournemouth on Tuesday, Wednesday, Thursday, and Friday, July 28, 29, 30 and 31, 1891. President, Dr. Willoughby Francis Wade. An Address in Medicine will be delivered by Thomas Lauder Brunton, M.D., F.R.S., Lecturer on Materia Medica and Therapeutics at St. Bartholomew's Hospital, London. An Address in Surgery will be delivered by John Chiene, M.D., F.R.C.S.Ed., Professor of Surgery at the University of Edinburgh. An Address in Public Medicine will be delivered by Edward Cox Seaton, M.D., Lecturer on Public Health at St. Thomas' Hospital, London.

The Long Island College Hospital, Brooklyn, announces that the regular course of lectures will hereafter be six months in duration, and three courses of lectures will be required for graduation. Joshua M. Van Cott, Jr., M.D., has been appointed Professor of Histology and Pathological Anatomy, vice Frank Ferguson, M.D., who has resigned.

Dr. William A. Hammond's Suit for Libel.—It will be generally remembered that the newspapers of the country recently reported that Dr. William A. Hammond, of Washington, D. C., had charged Senator Stanford $5,000 for removing a wen from his scalp. This is pronounced a criminal libel by Dr. Hammond, and he has had a warrant issued against Mr. William L. Crouse, Washington correspondent of the New York *World*, for sending such a libel for publication to his paper.

The Seventh Annual Meeting of the Fifth District Branch of the New York State Medical Association will be held in Wurzler's Building, 315 Washington Street, Brooklyn, Tuesday, May 26, 1891. The following papers are announced: President's Address, "Opiates in the Treatment of Acute Peritonitis," by Dr. Stephen Smith; "Cathartics in the Treatment of Acute Peritonitis," by Dr. A. Palmer Dudley; "The Treatment of Hydrocele by Carbolic Injection versus Radical Operation," by Dr. Samuel E. Milliken; "Scarlatinal Diphtheritis and its Treatment," by Dr. E. G. Rave; "Practical Results of the Operation for Lacerated Cervix Uteri," by Dr. H. W. Mitchell; "Objections to Ordinary Axis traction Instruments, also the Advantages of the Use of the Anticraniotomy Forceps over Version in Pelvic Deformities," by Dr. T. J. McGillicuddy; "A Case of Obstinate Neuralgia following Fracture relieved by Operation," by Dr. Reginald H. Sayre; "Acute Prostatitis and Prostatic Abscess," by Dr. William R. Ballou.

The California State Board of Health has recently been saddled with an attorney who gets $3,000 a year for his work, if he does any, while the members of the Board, with the exception of the secretary, get nothing.

Dr. Dewey's Change of Heart.—We have received the following candid and poetical acknowledgment of his change of views on the subject of antiseptics. We take pleasure in publishing them, and we hasten to add an expression of regret at having misspelled the name. Dr. Dewey writes: "Your criticism in the RECORD on my change of heart on microbes, is well taken.

> "Pure obstinacy in face of facts,
> Of ignorance and folly smacks.
> Mutations in this fickle age,
> Point to the statesman and the sage.
> The parasite has got on top,
> Whatever system we adopt,
> To kill the germ is all the go,
> To stifle it in embryo.
> Inventions that last one decade,
> Of very precious stuff are made.
> Water, the cheapest we can get,
> Has had no serious backset yet."

Cairo has an Epidemic of the dengue.

A British Pasteur Institute has been organized at Cambridge.

The Seventh International Congress of Hygiene and Demography will be held in London, from the 10th to the 17th of August, under the presidency of the Prince of Wales.

Dr. James N. Martin has been appointed Professor of Obstetrics and Diseases of Women at the University of Michigan. He filled the chair since Professor Dunster's death.

The Ninth Annual Commencement of the Woman's Medical College of Baltimore was held on May 1st, when diplomas were conferred on six graduates. Dr. Winslow, the Dean, delivered an address in which he told how the experiment of co-education was tried and failed. The story should be of interest to the Johns Hopkins' trustees.

Dr. G. Otis Pinero, of Elizabeth, N. J., died of heart disease, on May 19th.

New York Polyclinic.—At a meeting of the Faculty of the Polyclinic, held May 14th, Dr. Robert H. M. Dawbarn was elected to the Professorship in Surgical Anatomy and Operative Surgery.

Kansas City Medical College.—This college is one of the oldest west of the Mississippi, and has just completed its twenty-second annual session. The total number of matriculates was eighty, and the graduates, twenty-two for past session. Hereafter attendance upon a three-years' graded course will be required. To carry out this plan of instruction, additions will be made to the Faculty and a new lecture-room will be provided.

New York Post-Graduate Medical School.—At the meeting of the Directors of the New York Post-Graduate Medical School and Hospital, H. J. Boldt, M.D., was made Professor of Diseases of Women, William James Morton, M.D., Professor of Electro-Therapeutics, and Aug. Caille, M.D., Professor of Diseases of Children.

The German Congress of Internal Medicine continued its discussion on the use of tuberculin. The views expressed were faint in praise of its use. Professor Naunyn summed up the discussion. There was general agreement that diagnostically tuberculin was of less value than therapeutically. On the latter point observation varied essentially in laryngeal and pulmonary cases; for whereas no one had controverted the favorable results obtained in the former by Dr. Moritz Schmidt, on the latter there were most divergent views. On many sides there seemed to have been more favorable results at the clinics this winter; but whereas some of the speakers ascribed this solely to the action of tuberculin, others considered it due to the greater in-rush of patients seeking treatment, which yielded better statistics, which are not comparable with those of previous years. Dr. A. Fraenkel opened a discussion on "Angina Pectoris," with a paper which contained nothing new. Dr. Vierordt (Heidelberg) dealt with diagnosis, prognosis, and treatment of the disease. He noted the difficulty in differentiating it from cardiac asthma, and said some cases of angina passed into the latter. He distinguished (1) angina vera from sclerosis or syphilis of coronary arteries; (2) angina from organic heart disease, pericardial adhesion, aneurism; (3) toxic angina (lead and tobacco); (4) nervous, reflex, hysterical angina. In favor of organic angina (1 and 2) are the age of the patient and the presence of arterial sclerosis; while against it is the occurrence of an aura, the frequency of attacks, and the readiness with which they are borne. Prognosis is difficult and delusive in both the apparently slight as well as severe cases. The purely nervous form has a good prognosis, but that due to tobacco is less certain. Therapeutically, in nervous angina narcotics, especially morphine injections, should be used. In organic angina first stimulation should be employed (injections of camphor), and then careful use made of narcotics. Morphine holds the first place. In England nitrite of amyl and nitro-glycerine are much used, but Dr. Vierordt would not employ them in organic cases; they were preferably used in nervous angina, especially in the vaso-motor form. Derivatives to heart and extremities were often of value. In the intervals, iodide of potassium and regulation of exercise. As to pathogenesis, he could not admit the theory of cardiac weakness, since it was not always present, and it was more associated with cardiac asthma. He thought the attack rather due to the action on the heart of some unknown agency, which if the muscle be healthy excites pain alone, and if it be diseased causes both pain and weakness. Professor Quincke (Kiel) read notes of a case of hydrocephalus treated, with relief, by trephining and puncture (six times repeated during one month). In another case, with meningitic symptoms, he had produced improvement of symptoms, and finally recovery, by puncture of the subarachnoid space of the spinal cord which communicates with the cerebral ventricles. In another case of an adult with symptoms of cerebral compression, possibly due to chronic hydrocephalus, 80 c.c. of cerebro-spinal fluid were evacuated through puncture in the lumbar region, with improvement in symptoms. A Pravaz syringe is inserted between the arches of the third and fourth lumbar vertebræ, and introduced to a depth of about 2 ctm. in children, of from 4 to 6 ctm. in adults. The cauda equina being at this spot, there is no risk of injury to the cord. The operation is indicated in cases of acute rise in the cerebro spinal pressure, especially in tubercular meningitis. Perhaps permanent drainage of the spinal canal might be advantageous.

For Inebriate Women.—The articles of incorporation of the "Saint Saviour's Sanitarium" were filed last week in the office of the county clerk. The society's object is the reformation of inebriate women.

The Beth Israel Hospital is the name of a new hospital and dispensary opened on the East side.

A Very Nervous Plaintiff.—Last year, while travelling upon the Boston & Maine Railroad, Mr. George A. Matthews was injured. Subsequently he claimed that his nervous system had been shattered, and sues for $50,000 damages. As he cannot now bear to hear the rumble of cars nor the sound of escaping steam, he has secluded himself in a town in the hills some fifty miles from the seaboard. There thirteen lawyers and doctors gathered recently to listen to his deposition and to testify. It was found that he could ride in a carriage and sail in a sail ing-craft, whereupon the Boston & Maine people offered to furnish a team and a sailing yacht to Boston, two hundred and fifty miles, free of all expense to Matthews. In fact the railroad company demanded of him that he so travel and attend the trial in person, and the injured man agreed to do so.

A Quarrel Among Iowa Physicians.—Dr. G. M. Staples has served papers on Dr. J. F. McCarthy, in a suit for $10,000 damages. Both are prominent physicians of Dubuque. The suit grows out of the publication and distribution of a circular, containing numerous clippings from Dubuque papers, in which the names of Dr. Staples and other physicians appeared as surgeons or attendants in cases of accident or illness. Staples has always been a stickler for the enforcement of the Code of Medical Ethics, debarring physicians from advertising, and this circular was issued to show that the men who most emphatically insisted on the enforcement of the Code were the most liberally advertised, free of expense to themselves. This circular was distributed at the late meeting of the State Medical Association in Waterloo. Dr. McCarthy and other younger physicians, who believe in advertising, are charged with the authorship of the offensive circular.

The Great Hospital of the Polyclinico at Rome is uncompleted, and is in danger of being abandoned on account of the policy of retrenchment adopted by the Government.

The Prohibition of the Sale of Tuberculin in Munich has now been made absolute. Druggists are forbidden to sell it even to medical men.

The University of Pennsylvania, Medical Department, held its commencement on May 1st, and graduated a class of one hundred and thirty-three.

Mütter Course of Lectures on Surgical Pathology, of the College of Physicians of Philadelphia.—Professor Roswell Park, of Buffalo, N. Y., delivered Lectures VII., VIII., IX., and X., of the Mütter Course in the Hall of the College of Physicians of Philadelphia, on May 12, 13, 14, and 15, 1891.

Medical Legislation in Arkansas. — The Arkansas Legislature has enacted a law providing for the revocation of physicians' licenses for unprofessional conduct. The law is aimed chiefly at the Hot Springs physicians. Regarding this class, the *Journal of the Medical Society of Arkansas*, says: "Recently a physician visited Hot Springs and there met a doctor whom he had known in former years, and who was then poor but respectable. In response to the usual inquiry as to how the Hot Springs doctor was getting along, the latter replied that he was doing a regular '*cut-throat*' business, employed drummers, and 'stood in' with the hotel people, paying to the latter classes one half of all the fees collected from patients roped to him by them; that he had to keep a revolver in his desk all the time, because when patients found out they had been drummed they frequently returned to him and demanded their money, and he had to bluff them off and be prepared to defend himself; that all the Hot Springs drumming doctors did the same way, and added that they all drummed in one way or the other." It would look, from the above, as if the new Arkansas law had a rich field in which to exercise.

The French Surgical Congress, whose sessions began on March 30th, at the same time with that of their German *confrères*, was made interesting by communications from two Englishmen of somewhat antagonistic views, Sir Spencer Wells and Mr. Lawson Tait. Their common subject was oöphorectomy. Sir Spencer protested again against the present craze for doing it; he is satisfied that affections of the Fallopian tubes are much less common than is sometimes maintained, and he claims that salpingitis and pyosalpinx are curable without operation. Mr. Lawson Tait pleaded the innocuousness of salpingo-oöphorectomy, his figures yielding a mortality of only three per cent. He rejected the idea that castration produces premature old age, and maintained that the effects of the operation on the sexual appetite varied with the age at which it was performed—viz., before or after puberty. Of 271 castrations performed for uterine myoma, success was complete in 257. Performed before the age of forty, the operation determined the complete disappearance of the tumor 70 times out of 100. After forty years the myoma simply diminishes in volume by a sixth or a third. Formerly Mr. Tait entertained great doubts as to the expediency of castration for the cure of neurotic affections. Now, however, he believes the operation justifiable in epilepsy of menstrual origin, and he cited an instructive case of castration for menstrual insanity, in the person of the niece of a celebrated physician, in which the patient recovered completely.

A Successful Surgical Operation on a Centenarian.—Mr. W. H. Galland reports (*British Medical Journal*) a successful operation for the removal of an epithelioma from the lip of a man aged one hundred and two years.

The Prescription of Aconitine.—A medical practitioner of Montécouver, in France, was recently tried on a charge of "homicide by imprudence." The evidence showed that on December 21, 1890, he had prescribed 1 milligramme of aconitine for a young woman suffering from toothache. The patient was seized with colicky pains immediately after swallowing the dose, and died a few days later. The result of a *post-mortem* examination by a medico-legal expert led to the suspicion of aconitine poisoning, and it was at first supposed that the chemist who dispensed the drug had made a mistake; but after further investigation, the doctor was placed on his trial. Professor Brouardel gave evidence to the effect that the dosage of aconitine was not yet definitely settled, but that, in prescribing, medical men should follow the injunction given in the French Codex, and order only crystallized aconitine. The omission of this precaution led, according to Dr. Brouardel, to most dangerous confusion, to which he promised once more to call the attention of the Academy of Medicine. The defendant was fined 100 francs.

Investigating Ghosts.—The French Society of Physiological Psychology has appointed a committee to investigate the possibility of hearing the voices and seeing the counterfeit presentments of persons known to be far away at the time.

The Harvard Medical School Association was organized in Boston on April 30th. It is intended to include all graduates of Harvard Medical School. Dr. G. R. Chadwick was elected President, and Dr. R. W. Lovett, Secretary, and Dr. Walter Ela, Treasurer.

Vital Statistics for Maine.—"An Act to provide for the registration of vital statistics" was passed at the session of the Maine Legislature just closed. The act will take effect on the first day of January, 1892.

A New Antiseptic.—At the Académie de Médecine, on April 28th, M. Polaillon read a paper contributed by Dr. Berlioz, of Grenoble, on a new antiseptic agent called "microcidine," which is composed of seventy-five per cent. of naphtholate of sodium and twenty-five per cent. of naphthol and phenyl compounds. It is a white powder obtained by adding to fused β-naphthol half its weight of caustic soda, and allowing the mixture to cool. It is soluble in three parts of water, and the solution, which is cheap, is said to possess considerable antiseptic powers, without being toxic or caustic or injurious to instruments or linen. The antiseptic properties of microcidine, while inferior to those of corrosive sublimate or naphthol, surpass those of carbolic and boracic acids ten and twenty times, respectively. Microcidine is eliminated by the kidneys, and is antipyretic. M. Polaillon has experimented with this new agent largely in his wards as a dressing to recent and other wounds, utilizing as a dressing, after a preliminary cleansing of the raw surface with a three per cent. solution, gauze soaked in the same and covered with a layer of oil silk and a thick pad of cotton-wool. The results are reported to have been excellent.—*Lancet.*

Congress for the Study of Tuberculosis.—The programme of the Second Congress on Tuberculosis, which will take place in Paris from July 27th to August 2d, under the presidency of Professor Villemin, comprises the following subjects: 1, On the identity of human tuberculosis with that of bovines, the gallinacea, and other animals; 2, the bacterial and morbid associations of tuberculosis; 3, on hospital treatment of the tuberculous; 4, prophylaxis of tuberculosis in man and animals; 5, agents which are capable of destroying Koch's bacillus without injury to the organism, in regard to the prophylaxis and treatment of human and animal tuberculosis.

Medical Hats. — It is proposed by certain German physicians that medical coachmen, or rather the coachmen of medical men, be distinguished by wearing white hats.

St. Louis Medical College has been made the Medical Department of Washington University. The college will soon erect a new building.

New Procedure in Abscess Treatment.—The treatment of chronic or cold abscess by the method of aspiration and injection of antiseptic solutions, such as iodoform dissolved in ether, is a favorite plan of some French surgeons, and is the one usually adopted for some time past in the wards of M. Verneuil, now the Senior Professor of Clinical Surgery in the Paris Faculty; but it appears to have been reserved in France to Dr. Piéchaud, of Bordeaux, to have adapted the method with success to the treatment of acute inflammatory abscesses. Instead of the time-honored free incision of the most dependent part Dr. Piéchaud aspirates the abscess, after which he injects a solution of 1 in 1,000 of corrosive sublimate. For the past ten months he has invariably adopted this method in his hospital practice, and, he declares, with marked success. Even if the skin over the seat of the abscess be thinned and undermined, this is no bar to the procedure, for which he claims as advantages that it is less painful, leads to more rapid healing, and leaves no traces of scar. —*The Lancet.*

Important Improvement in Microscope Lenses.—It is stated that an immense improvement has recently been effected in the manufacture of glass for optical instruments by means of the addition to the ordinary materials of phosphorus and chlorine, which in some as yet unexplained way cause the glass to be very much more transparent, and enable it to receive a much higher degree of polish than any optical glass hitherto manufactured. Thus microscopes can be made which will render objects of the diameter of only the one-eight millionth of a millimetre visible, whereas with the best instruments now in use the diameter of the smallest object that can be seen is one-sixteen thousandth of a millimetre.

Reviews and Notices of Books.

Hereditary Health and Personal Beauty. By John V. Shoemaker, A.M., M.D., etc. 8vo., pp. 422. Philadelphia: F. A. Davis. 1890.

This book is written primarily for the laity, but will prove of interest to the physician as well. The author has been too long before the public to need any introduction, and any criticism of style would be out of the purview of this notice. He here discusses the general laws of health in their relations to the regulative laws of life and growth. Special chapters are devoted to man's spiritual and physical place in Nature. The topic of the effect of environment on physique is elaborated at some length. The practical part of the book is given up to chapters on the bath, care of the skin, hands, feet, nails, hair, teeth and nose, clothing, etc., with sensible remarks on ventilation and other popular topics now so widely discussed. A somewhat extensive formulary of cosmetic articles, medicated soaps, and household remedies is appended.

These various subjects are discussed from their moral as well as physical aspect. Though the author goes to some extent into technicalities, he confines himself to the use of good, plain English, and in that respect sets a notable example to many other writers on similar subjects. Furthermore, the book is written from a thoroughly American stand-point.

Wood's Medical and Surgical Monographs for March, 1891. Contents: "The Modern Diagnosis of Diseases of the Stomach," by J. M. Purser, M.D., Dublin; "Unsoundness of Mind in its Legal and Medical Considerations," by J. W. Hume Williams, of London; "Baldness and Grayness, their Etiology, Pathology, and Treatment," by Tom Robinson, M.D., London. Pp. 293. Single copies $1; per year, $10. New York: William Wood & Co.

The three articles contained in the March number of "Wood's Monographs" are deserving of extended praise, as they are all excellent. The one on the diagnosis of diseases of the stomach, however, will probably be most welcome to the greater part of the profession, as it gives easy and practical methods of examination of stomach contents. Any practitioner can determine hydrochloric acid, pepsin, and other substances, a knowledge of which is so useful and sometimes necessary in the differential diagnosis of cancer. Medical jurisprudence is a much neglected branch of study in most colleges, and so excellent an addition to it as is Mr. Williams's paper on "Unsoundness of Mind" will be eagerly studied by the thousands who read the monographs.

Manual of the Domestic Hygiene of the Child, for the Use of Students, Physicians, Sanitary Officials, Teachers, and Mothers. By Julius Uffelmann, M.D., Professor of Internal Medicine at the University of Rostock. Translated by Harriot Ransom Milinowski. Edited by Mary Putnam-Jacobi, M.D. Pp. viii.–229. New York and London: G. P. Putnam's Sons.

The market is loaded with "Manuals of Nursing," "Hints to Mothers," etc., and the question of the care of the baby is exhaustively treated, but strange to say comparatively little cognizance is taken of the child from his weaning to puberty. This period is beset with special ills and is deserving of more attention than it receives. Professor Uffelmann's book is complete. It takes the child from the moment of birth and considers it from a hygienic stand-point to adolescence. The matter is excellent. Nothing is stated empirically, but the whys and wherefores are discussed, and deductions are based on facts and on clinical experience. The chapter on nourishment is worth the price of the book several times over. The book has an unique position, being designed for both professional and non-professional readers. This end is obtained by placing statistics, tables, and technical matters in footnotes, to which the professional reader can refer, and leaving the text clear. The book ought to be in the hands of every mother. The editor and translator have both added much of value to the book. The translator's work is deserving of praise.

The Post-Graduate Clinical Charts, Designed for Use in Hospitals and Private Practice. Arranged and published by William C. Bailey, M.D., and J. H. Linsley, M.D. New York: J. H. Linsley & William C. Bailey. 1891.

These clinical charts have been carefully and ingeniously prepared, and are superior in very many ways to any similar devices for keeping accurate records. The charts come in sets of ten. The first two contain figures for marking out the seat of lesions in the thoracic and abdominal cavities, and on the vocal cords.

Then follow temperature, pulse, and respiration charts, and finally charts for recording the general progress of the case. By the use of the methods furnished by charts like these careful records are much more surely obtained, and the final study and analysis of cases can be more easily made. Drs. Linsley and Bailey have furnished the profession a very serviceable help in clinical work.

Society Reports.

American Medical Association.

FORTY-SECOND ANNUAL MEETING.

Held in Washington, D. C., Tuesday, Wednesday, Thursday, and Friday, May 5, 6, 7, and 8, 1891.

(Continued from page 579.)

SURGICAL SECTION.

SECOND DAY, WEDNESDAY, MAY 6TH.

Traumatism of the Chest.—DR. J. MCF. GASTON, of Atlanta, Ga., read a paper with the above title. He pointed out the lack of definite instruction to be found in the text-books on surgery relative to traumatisms of the chest, and the necessity of more definite knowledge. He divided the subject into: 1, foreign bodies in the trachea and bronchi; 2, blows affecting the functions of the heart and lungs; and 3, punctured wounds. The literature of the subject was then reviewed, and the treatment of the first two divisions of the subject discussed. In punctured wounds the question had always been as to whether the wound should be closed or left open, and it had generally been held that when the hemorrhage into the pleural cavity was slight in amount the wound might be closed, but where the hemorrhage was considerable the wound should not be closed. With this Dr. Gaston took issue. He advised that all wounds should be closed and hermetically sealed. If there was much blood in the pleural cavity, as much as possible should be removed, the chest compressed by a firm bandage, and the wound closed and sealed. In large accumulations of blood he said it seemed probable that absorption of the clot took place. If it did not, the case could be treated as an ordinary case of pleuritic effusion. Unless air had entered the pleuritic cavity suppuration was not to be expected. In cases of hernia of lung-tissue he advised the use of the elastic ligature.

DR. ANDREWS, of Chicago, said that some cases did well whatever the treatment, and that other cases did not do well, apparently because air was drawn into the pleural cavity from the wound in the lung.

DR. MYNTER, of Buffalo, referred to the advice of some recent German writer, who advised in those cases where there is no wound in the lung, to fill the pleural cavity with a boric-acid solution, seal the wound, and then aspirate the artificial pleuritic effusion in the ordinary way, with the idea of allowing re-expansion of the lung.

DR. RICKETTS, of Cincinnati, said the same thing could be effected by over-distending the wound in the chest wall by a rubber tube, washing out the pleural cavity through this, and the closing the tube by a ligature.

The Surgical Use of Aristol.—DR. W. C. WILE, of Danbury, Conn., reviewed the literature of the subject, and reported in detail several cases in which he had used the drug with the most happy results. He said that in all recent wounds, where the cleanliness was reasonably good, the use of aristol gave the best results. At the first dressing there would be found to be no exudation, the aristol would be dry, and the wound would be dry. It had many advantages over iodoform. It is not poisonous, it has no odor, it does not irritate, and is fully as antiseptic as iodoform.

DR. ROBERT NEWMAN, of New York, said that he had experimented extensively with aristol, and related his experiments to prove that the drug is not absorbed.

Peritonitis from a Surgical Standpoint.—DR. MORDECAI PRICE, of Philadelphia, said that idiopathic peritonitis was a myth and a delusion; and that the opium treatment is so, the most of all, in that it blinds the surgeon to the rational and proper treatment. He said that the disease is so peculiarly surgical that we do not need to resort to the dead-house to learn our pathology—the pathology is learned on the operating-table. The symptoms of peritonitis are: A chill, but this is not constant; a high temperature, but this is not always present; pain, which may be so slight as not to be complained of; the pulse may be weak in the beginning, or soon become hard and tense; tympanites not always present; a facial expression of anxiety, which is by far the most constant and characteristic symptom; constipation is always present, and should be an indication to the practitioner that opium is unnecessary. He believed that there was always an irritating cause, and that the cause can be demonstrated.

He had operated, or assisted at the operation, by abdominal section, in five hundred cases of peritonitis during the past five years. All were suppurative cases, and all would have died. In all cases a well-defined cause was found. There was not one case of idiopathic peritonitis. In not one case of the series did peritonitis follow the operation. He considered disease of the uterine appendages as the most frequent cause; next, appendicitis; and next, meddlesome gynecology.

Treatment should be to first search for the cause, and having found it, remove it. If the cause cannot be found the case should be cleared up by the administration of saline purgatives. If under the use of salines the distention does not disappear, and the temperature fall below the pus standpoint, operation is imperatively demanded.

DR. QUIMBY, of New Jersey, believed that many primary cases could be cured without operation by proper preliminary treatment. His treatment consists of a combined use of opium and calomel, and the application of poultices. In twenty five years he had not lost one case under this treatment. Hoffman, of Philadelphia, said that more than one has been killed by the distention of the intestine by gas. Opium paralyzes the intestine, favors distention, and checks the secretions. If a patient recovers under the opium treatment, he recovers not because of the opium, but in spite of it.

DR. DAVIS, of Birmingham, Ala., often used calomel purgation instead of the salines; and he frequently flushes out the intestine as well as the abdominal cavity.

DR. BALDY, of Philadelphia, agreed in the main with the writer of the paper, but he believed that cases not relieved by salines do get well under rest treatment. On the other hand general purulent peritonitis never gets well under any treatment whatsoever. He believed that four hundred and fifty out of five hundred cases of peritonitis would get well without operative measures.

DR. PRICE said that four hundred out of his five hundred cases were at the point of death when operated upon, and that all were suppurative cases. He did not operate unless there was pus, and he believed that salines and calomel will cure nine out of ten non-suppurating cases. In traumatic cases he believed that operative measures were always demanded.

The Relation of Concussion of the Brain and Spinal Cord to Inflammatory and other Morbid Changes in these Organs.—DR. B. A. WATSON, of Jersey City, N. J., presented a very exhaustive paper upon this subject. The paper was so long, however, that the conclusions were not reached when the reading was terminated by the time-limit. The paper was based upon one hundred and forty-one experiments aimed to produce concussion of the spinal cord, and the author is convinced that to produce such concussion a very severe blow must be inflicted, inasmuch as the spinal cord is the most difficult organ in the body to be affected by concussion. In some of his experiments the microscope demonstrated a lesion where none was discernible to the naked eye. Of course in fractures and dislocations the injury to the cord is obvious. In true concussion but slight symptoms are present, and the concussion does not give rise to any inflammatory action. By true concussion he means concussion by vibratory action, and he draws a line between concussion and contusion. Suppuration as well as in-

flammation may result from contusion, but not from concussion.

Is Early Resection or Conservative Treatment Advisable in Coxitis?—Dr. Herman Mynter, of Buffalo, N. Y., answered his own question in favor of resection. He reviewed the pathology of Volkmann and Koenig, showing that the primary focus of the joint disease is nearly always located in the bone, and upon these premises founded his argument and drew the deductions for removal of the diseased focus by operative measures at the earliest possible moment. He admitted that coxitis, in any stage, may recover without operation, but asserted that all cases treated conservatively recovered with more or less flexion and adduction. He reported upon ten cases operated upon by himself, and stated his belief that by an early operation, and only by an operation, the disease could be arrested, the mortality reduced, and that rapid healing of the wound and a movable joint could be confidently anticipated, with no flexion, adduction, or other deformity than slight shortening, and that the functions of the limb were far better than could be obtained by conservative treatment. In addition, and not an unimportant point, the patient was relieved from years of suffering and treatment. He exhibited the specimens removed from two recent cases. One had suffered but four, and the other six, weeks prior to the operation; both showed the primary focus to have been in the bone, and both were suppurative cases. Both cases had recovered, and had been discharged from the hospital at the end of three weeks.

Dr. W. R. Townsend, of New York, did not believe that disease had existed only four and six weeks in the cases whose specimens were presented, and he did not consider them as cases that could properly be called early cases. He denied the charge that all, or most, cases of coxitis treated by proper mechanical means aimed to give physiological rest to the joint, recover with flexion and adduction, or that the functional results following operation were better than those obtained by conservative treatment. He referred to his own large experience in the management of hip cases, and compared it to the small experience of the author of the paper, and held that Dr. Mynter's conclusions should not be accepted as conclusive.

Dr. R. H. Sayre, of New York, agreed in the main with Dr. Townsend, and held that under proper mechanical treatment, good diet, and hygienic surroundings, patients almost invariably recover with good joints. Only cases that do badly under proper conservative treatment should be subjected to operative measures.

Dr. Ridlon, of New York, agreed with Drs. Townsend and Sayre; he accepted the pathology of the author, but held that that did not prove that the patient would not recover without the operation, or that he would recover with the operation. He referred to the work of Wright, of Manchester, Eng., who has done more excisions during the early stage than any other surgeon, and asserted that Wright admitted that relapses were not infrequent after the results of the operation had remained sound for as long as two years. Bearing on the functional results obtained by excision, he referred to the half-dozen cases exhibited by von Bergmann in his clinic, on the occasion of the International Congress, at Berlin, last August, and asserted that they all showed flexion as well as shortening, and some had adduction. He pointed out, as a cause of relapses after operative measures, the failure to remove the primary tubercular focus in the patient—usually in the bronchial lymph-nodes—though the primary focus in the joint had been removed, the fact that cases after operation were not given prolonged mechanical support until all unsoundness had passed away from the joint, and the locality no longer furnished a better field than any other part for the tubercular seed derived from the cheesy lymphatic glands. He suggested that those anxious, from logical deductions rather than clinical experience, to remove the primary focus, should remove the bronchial lymph-nodes; and said that early removal of the primary bone lesion to eradicate the disease could be compared with laparotomy to remove Peyer's patches as a means of cure for typhoid fever.

In conclusion, Dr. Mynter did not by any means accept the logic of his friends, the orthopedists, and held that if his pathology was accepted, operation must be the logical conclusion of any intelligent mind. He regarded the tubercular bacillus as not pathogenic, and suppuration as purely an accidental infection.

Third Day, Thursday, May 7th.

Cadaver Studies on the Removal of the Semilunar Ganglion through the Floor of the Cranium.—Dr. Edmund Andrews, of Chicago, said that the frequent relapses after resection of portions of the fifth nerve for facial neuralgia had led to these studies. He had found repeated relief, often of months' duration, from opening up the wound after resection and pulling on the stump of the nerve. He believed that the persistence of the neuralgia was due to a neuritis of the dental nerve, extending up the nerve from a decayed tooth to the semilunar ganglion, and from thence the other branches of the nerve became affected. To eradicate the disease it would therefore seem desirable to excise the ganglion. Professor Rose, of Kings College, London, Eng., seems to have been working in the same direction at the same time, and was the first to operate upon the living subject. The manner of performing the operation, as done by Rose, was explained, as well as the anatomy of the part. Dr. Andrews advises the following operation: The nerve is exposed by sawing through the zygomatic arch at either side and turning it up together with the temporal muscle, and then sawing off the coronoid process and turning it down together with the masseter muscle. The nerve is then followed up and the base of the skull perforated by a trephine having a blunt pin, a cutting diameter of about two centimetres, and a handle sufficiently long to escape contact with the muscles. The round, blunt centre-pin is inserted into the canal, and the button of bone having been removed, the ganglion is exposed. It lies between two layers of dura mater; is readily separated from that next the skull, but is very adherent to that next the brain. The small hook-knife of Professor Rose is used in making section of the nerve-branches. Considerable traction upon the ganglion by pulling on the nerve can be exercised with safety.

On Deaths from Chloroform and Ether, since the Hyderabad Commission, with Conclusions Drawn from Them.—Dr. Lawrence Turnbull, of Philadelphia, presented elaborate tables upon this subject. The whole number of deaths reported since the report of the Hyderabad Commission was 43; 39 from chloroform, 4 from ether. The exceeding small number of deaths from ether demonstrates its great safety. Still, that it will kill, and does kill, and does kill from the heart cannot be doubted.

Dr. B. A. Watson, of Jersey City, referred to the lowering of the temperature, in the use of ether, of at least 1°, but in the use of chloroform to a still greater degree. This is the reason why he will continue to use ether.

Dr. Hunter Maguire, of Richmond, in answer to a question by Dr. Edmund Andrews, said that he had himself administered, or had had administered for himself, chloroform over one thousand four hundred times, and that in his brigade of the Confederate army chloroform was administered over two thousand eight hundred times, all without one death from the chloroform. One case, a woman, died from fright. He believed that the danger in chloroform was in its rapid administration. Chloroform is dangerous; ether is less so. In weak heart, from any cause whatsoever, ether is safer; in fatty heart, renal disease, and bronchial disease, chloroform is safer.

Dr. Wyeth, of New York, referred to the Ormsby inhaler as rendering the administration of ether much safer,

half an ounce of ether being sufficient to anæsthetize a patient for an hour.

Linear Craniotomy for Defective Mental Development.—Dr. W. W. Keen, of Philadelphia, reported that his first case, already published, showed a steady improvement in mental condition, but less than that reported of the cases of Lannelongue.

In his second case, no fontanelle existed at birth; the only other child of the family, an older brother, was hydrocephalic. Some time after having made the linear craniotomy upon one side, he made a second operation upon the other side of the head. There had been a slight but steady progress in mental development.

His third case had died suddenly about an hour and a half after the operation, when everything seemed to be going on well. The cause of death was not ascertained, as an autopsy was refused.

The fourth case, that of Gerster and Sachs, of New York, had died of anæmia three and a half hours after the operation.

The fifth case was that of Wyeth, of New York. In this case linear craniotomy was made on both sides, and from each end of each furrow another furrow was made downward, and the lateral bone-flaps were then pulled apart by the inserted fingers, spreading the quarter of an inch furrow to about an inch. The case recovered, and the mental improvement was reported to be marked.

The sixth and seventh cases were those of Lannelongue.

Dr. Keen regarded the operation as justifiable, as even death was preferable to a continuance of the condition in the bad cases. He regarded it as safer to operate at different times on both sides of the skull than to do both operations at the same time; and he also thought it safer not to practise the divulsion of Wyeth, as the dura mater is usually very adherent in children. Recently McClintock, of Kansas, had operated by Wyeth's method, making in all eight cases. The patient was alive, but the operation was too recent to report upon the mental progress.

By the use of the cutting forceps devised by Dr. Keen, he was now able to do a single linear craniotomy in twenty minutes, whereas in his first case it had taken him seventy minutes. This he considered as of great importance, inasmuch as the defective circulation in these cases contraindicated prolonged anæsthesia.

Dr. Wyeth, of New York, said that he agreed that it was safer to open both sides by successive operations, instead of both at the same operation, as he had done in his first case. He has, since his first case, made the unilateral operation in two cases. He, however, believes that the tearing open of the furrow has been the reason for the rapid improvement in his case.

Dr. Pancoast, of Philadelphia, queried whether rapid brain expansion could be expected when the firm dura mater still enclosed the brain.

Dr. Thomas, of Pittsburg, Pa., said that in judging of the operation the clinical history of untreated cases should be considered. He had a microcephalic patient who did not walk until four years of age, and did not talk until he was five, who now, at ten years, was as bright as the average boy of that age. He had another case that did not notice things until he was four, and now, at seven years, he was in some respects a genius. He believed that many will recover perfectly without operation.

Dr. Keen said that the operation had seemed somewhat illogical, inasmuch as the firm dura mater remains intact, and it is well known that the bony parts mould themselves upon the soft parts. And this was one reason for opposing the immediate divulsion, and he would rather so arrange his operation as to persuade the brain to develop gradually.

Exploratory Incision in Cases of Fracture of the Bones where Doubt Exists as to Their Character.—Dr. B. M. Ricketts, of Cincinnati, O., reported upon his experiments in the lower animals. He believes that union is more slow after the use of the saw than after the use of the knife; that where a knife cannot be used, a chisel should be selected. In those cases where a saw must be used, the finest obtainable saw should be selected. In compound comminuted fractures the fragments should not be removed, but should be carefully replaced, and if necessary wired with silver wire, in order to restore as nearly as possible the normal contour of the limb. In compound fractures he uses a boiled water dressing, frequently renewed.

Dr. R. T. Morris, of New York, preferred bone dowels, sterilized by dry heat, and silkworm gut.

Sprains of the Ankle.—Dr. W. R. Townsend, of New York, referred extensively to the writings of Monsell Moulin, Whitman, McCurdy, and others, and held that every sprain was worthy of careful surgical treatment until cured. His treatment consists of support to the part, rest, and restoration of joint function. He elevates the leg to reduce swelling, and a snug dressing of strips of adhesive plaster, cut from one to one and a half inch wide. Over this a roller bandage is placed, and the patient allowed to walk in the milder cases. In the more severe cases he adds a plaster-of-Paris or silicate splint. The dressing should be frequently renewed, and motion allowed as soon as possible to prevent adhesions within the joint. Later he gives hot and cold douches, and massage.

Supra-pubic Cystotomy.—Dr. J. A. Wyeth, of New York, reported in detail upon twenty-three cases, and then gave a description of the operation with such clear and careful attention to every minutiæ of detail, that it seemed that one not a surgeon might readily and safely perform the operation. He believes that for the thorough digital exploration of the bladder, for the removal of tumors, and for temporary or permanent drainage of the bladder, it is far superior to the perineal operation. For removal of stone or foreign body, it is so safe and satisfactory that he prefers it to the low operation.

Dr. Keen, of Philadelphia, commended the operation, and Trendelenburg's position for all pelvic operations, and pointed out the ease with which, having opened the bladder above the pubes, it was possible to catheterize the ureters.

Dr. Hunter Maguire, of Richmond, makes the urine acid by causing the patient to drink lemonade before operating, he does not use stitches, and for a permanent opening uses a silver plug.

Dr. Davis, of Birmingham, Ala., considered stitching unnecessary; and said that the silver plug was first used by his brother.

Dr. R. T. Morris, of New York, turns in skin flaps for a permanent opening; and uses a wick of gauze rolled in Lister protective, in place of a catheter, for drainage.

Dr. Palmer, of Wisconsin, simplifies the operation by introducing a large curved steel sound, per urethra, and cutting down upon its tip.

Dr. Deaver, of Philadelphia, considered the perineal operation safer and more rapid.

Dr. McRae, of Atlanta, Ga., uses saccharine internally to acidify the urine.

Dr. Wyeth said that he only used stitches when he desired to close the opening at once.

Platinum Needles for Electrolysis.—Dr. Robert Newman read a paper upon this subject; showed good and bad needles, and pointed out their difference, and told where the only good needles could be obtained in this country. The advantage of platinum, as a metal, for this use is that it is not oxydized or decomposed by electrolytic action, and this more than compensates for the fault that the metal is so easily bent.

The following officers were elected for the ensuing year: Chairman, Dr. J. McF. Gaston, of Atlanta, Ga.; Vice-chairman, Dr. Mordecai Price, of Philadelphia, Pa.; Secretary, Dr. F. W. Mann, of Detroit, Mich.

SECTION ON DISEASES OF CHILDREN.

FIRST DAY, TUESDAY, MAY 5TH.

WILLIAM PERRY WATSON, M.D., OF JERSEY CITY, CHAIRMAN.

The Sterilization of Milk and the Status of Our Knowledge upon the Subject, with Bacterial Demonstration.—DR. HENRY KOPLIK, of New York, read a paper on this subject. It is a positive fact that milk, as it comes from the cow, contains no bacteria. Its impurities get in later from various sources and consist of straw, dirt from the hands, manure-specks, etc. These exist, of course, in varying amounts in different specimens, and hence the great variations in the results of bacteriological investigations as to the number of germs which milk contains.

Pasteur found that the lactic acid fermentation with the separation of the casein was due to a specific microbe, without the presence of which the process could not occur, and furthermore, that these came from the air. If the latter was shut out the process did not occur. Even if milk was subjected to a temperature of 100° C., an alkaline fermentation might occur later, and this was probably of a butyric nature. If the temperature was raised to 230° F., and with a pressure of one and one-half atmospheres, no infusoria, bacilli, or germs of any kind were left in the milk. But there are practical disadvantages in using such milk as an infant food, even though it may be germ-free and theoretically just what we ought to use. It has been found by several observers that the casein undergoes some change in the various heat processes of sterilization by which its digestibility is affected, just how or why we cannot say. Some of these facts have been lost sight of in the great deluge of apparatus which has flooded the market. The ordinary methods of household sterilization are often faulty, and the mere fact that milk has been so treated that it will not sour if allowed to stand is by no means a full solution of the problem of making it an ideal food for an infant. It may later undergo an alkaline fermentation. This is probably often due to the common potato-germ which is everywhere about the farm and dairy, and which, along with its spores, does not succumb to that degree of heat which is sufficient to kill the lactic acid germ. Milk sterilized, so-called, will nevertheless grow certain other germs. While these latter can be destroyed, this very process of destruction renders the milk unfit for feeding to children, and hence our dilemma. It is of importance that the milk-containing vessels should be subjected to live steam, for at least twenty minutes, and forty-five minutes are really necessary for absolute safety. In the butyric fermentation, bubbles of carbonic acid gas were often formed. In some specimens crystals of leucin and tyrosine, along with peptone, were found. In these latter cases the culture-tube showed a cream zone at the top, then a clear watery mass, and at the bottom these crystals. This same peptone has resulted when milk has been inoculated with the streptococcus pyogenes. The germs of typhus, tuberculosis, diphtheria, and cholera all grow in milk without markedly changing its general characteristics. Fortunately, however, under ordinary circumstances, milk which is sterilized under the usual methods is safe to use, if it has been placed in the hands of the consumer with ordinary cleanliness, has been sterilized with live steam for thirty-five minutes, kept stoppered, and not kept too long. The bacteria of the alkaline fermentation are slow to develop, and hence, if the milk is daily prepared and each steamed product not kept over twenty-four hours, practically danger is avoided. The storage of sterilized milk is to be condemned, for fear of the later deleterious changes. It is not safe to use old preparations.

Concerning the digestibility of sterilized milk, much yet remained to be learned. Some had had success by adding pancreatin before steaming. Dr. Koplik preferred to add it after steaming, but before feeding. In selecting the amount for each meal we were to be guided neither exclusively by weight or age, but by the relation of the general condition of our patient to that of the average healthy child of the same age. Practically the various steam-cookers gave no better results than the ordinary kitchen utensils. The bottles should be placed in the utensil used and steamed ten minutes with their mouths uncorked, so as to expel all the residual air; then corked and steamed for forty-five minutes longer. Ordinary cotton batting, after being baked, made good stoppers. Absorbent cotton should never be used. A more careful supervision of dairies and the care of the milk while *en route* to the consumer would greatly simplify the problem.

The Chemistry and Clinical Value of Sterilized Milk.—DR. E. P. DAVIS, of Philadelphia, read a paper on this subject, giving the results of a series of chemical tests by Professor A. R. Leeds, with clinical observations of his own. Professor Leeds had found that in milk there were three classes of substances: 1. In suspension, nuclein (containing phosphorus), fat-globules, but without an albuminous envelope as has previously been believed, and floating in a ropy, mucilaginous fluid. 2. Casein and lact-albumin (colloidal bodies). 3. In solution, salts, soluble compounds of phosphoric acid, milk-sugar, and a starch-liquefying ferment. By sterilizing, the starch-liquefying ferment was destroyed, and coagulation followed. The lact-albumin was partially coagulated, thickening the milk and making it more ropy. The fat-globules were affected by heat so that the coagulated proteid material was attracted to them, and other minor changes were noted. The milk sugar was, by long heating, completely destroyed. The general conclusion was, that sterilized milk was less perfectly and completely digested than normal milk.

Dr. Davis's method, as used extensively by him, was to render the milk feebly alkaline by lime-water, then to raise the temperature to about 155° F. for six minutes, and if the preparation was not to be used immediately to heat it up to the boiling-point for a very brief period. Pancreatin was in all cases used. The later excess of heat stopped its action. He had used intestinal irrigation and antiseptics, and the three agencies combined had rendered him excellent service among a very unpromising class of patients. Constipation had sometimes resulted from sterilization. Cod-liver oil, especially when given with small doses of Fowler's solution, had been well assimilated in the foregoing cases. Some fed on the milk alone had benefited only temporarily, and had seemed to gradually perish of starvation; autopsy showed highly atrophic changes in all the organs. The prepared milk often served a useful purpose in supplementing a deficient supply of breast-milk, but infants were apt to do poorly on it when confined to it entirely.

DR. J. LEWIS SMITH, of New York, spoke of the various methods of dairy contamination. Yet, with all our imperfect manipulations of these later years, we had vastly reduced the infant mortality among foundlings and city children of all social grades. He believed that a two hours' exposure to boiling water was often necessary.

DR. E. F. BRUSH, of Mount Vernon, N. Y., did not believe that the souring of milk was its greatest danger. In all cud-chewing animals the young first swallowed the milk and of course it coagulated. It was then regurgitated and the curd chewed, after which it was again swallowed. The rennet coagulum was a softer one than the one formed with acid. He had often had his patients use milk soured after a thunder-storm and in a condition of "clabber," by beating it up thoroughly, and children fed thereon had suffered no harm. This procedure was by no means to be always advised. The rapid cooling of milk over cold tubes he regarded as highly objectionable. It would keep longer, but did not agree so well with children. He had not found by experiment that milk-sugar was completely destroyed by the alcoholic fermentation. As he had before stated at other

times, he believed that sterilization "devitalized" milk, though we did not know just what this process of devitalization was. Calves fed on normal milk had soft, large, yellow livers, while those fed on any of the artificial calves' foods had livers which were small, hard, and dark-colored, though they might be as fat as the others. This change in the inner organs was evidently due to their devitalized diet. An analogy was found in the liability to scurvy when the supply of fresh foods was cut off at his own farm. His cows kept for milking were all spayed. No animal should be used both for breeding and for milking. If consumers would pay more for milk and less for substances to put into milk, the dairyman could put a better and safer article on the market.

Dr. S. S. Adams, of Washington, D. C., had used milk which had been sterilized for ten days, with only good results. He believed that the preferable method was to dilute and scald it. He did not believe that sterilization necessarily caused or implied devitalization. We must judge of our results in private families, and not in hospitals, to form a fair estimate of any process. He used oatmeal-water in cases of constipation, and barley-water to break up the curd.

Dr. Simon Baruch believed that the lack of hydrochloric acid in the secretions of the child's stomach was the cause of most of the difficulty. In all households one bottle from each lot prepared should be set aside for one week, and its subsequent changes (if any) noted. In that way we could judge of the efficiency of our methods.

Dr. T. S. Latimer, of Baltimore, thought we laid too much stress on sterilization as a finality, rather than as one important link in a chain of conditions. The variation in weight, rather than the absolute weight itself, should guide us in our selection of the amount to be given at each feeding.

Dr. Bryce, of Toronto, gave an account of the process followed on a dairy farm near that city. The milk was received into clean vessels, filtered, and rapidly cooled to 45° or 50° F. within thirty minutes. By this process all the animal odors were removed. It was then kept in a refrigerator and delivered to the consumer within twenty-four hours. Used as delivered, without any further manipulation, it had given most excellent results after a three years' trial.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

THE VALUE OF TUBERCULIN IN SURGERY—THE EXTENSIONS OF THE MEDICAL CURRICULUM—CERTIFYING FACTORY SURGEONS—OPPOSITION TO THE NEW SCHEME FOR THE UNIVERSITY OF LONDON.

London, May 2, 1891.

An important communication on the value of tuberculin in surgery was presented to the Medical and Chirurgical Society at its last meeting by Mr. Watson Cheyne. The author said that in most of his cases he had adopted the mode of administration recommended by Dr. Koch (in which the occurrence of reactions was the guide to the dose), but that there were objections to this method and that he had for some time been employing another. This consisted in establishing tolerance as regarded the general action of the remedy as quickly as possible, and then repeating the doses in rapid succession so as to keep up a constant local action. If, for example, an initial dose of 2 milligr. produced fever, a second dose of the same amount was given as soon as the fever had subsided—probably in two days; so with a third. In most cases after four or five injections no further reaction occurred with this dose. The same dose was then given twice, and, after a few days thrice, daily The amount was afterward increased till ultimately doses of from one to two or more decigrammes were given three times a day. Mr. Cheyne believed that in this way a large amount of the fluid could be introduced rapidly without the patient suffering from fever after the first three or four doses, and with marked improvement as regarded the local condition. Another plan was to give large doses at long intervals, so as to avoid the establishment of tolerance. Mr. Cheyne condemned the method in common use of giving small doses at considerable intervals for the reason that it was hardly likely to do any good; it was also not unlikely to increase the risk of dissemination of the disease. The author pointed out, however, that the danger of dissemination of the disease had been greatly exaggerated, and that the main danger was where the tubercular disease was combined with sepsis, and was due to extension, not of the tubercular, but of the septic process. Passing on to the consideration of what the treatment could do Mr. Cheyne said he had come to the conclusion that in the majority of cases its first effect was to produce improvement as regarded the tubercular disease, the degree of improvement varying according to the circumstances of the case and the mode of application of the remedy; but that this improvement rarely went on to complete cure unless aided by other measures. In most cases, improvement came to a standstill after a time, and, if the treatment were given up at this stage, or within three months and a half (the limit of Mr. Cheyne's experience), relapse would almost certainly occur. The great question—one, however, which affected medicine more than surgery—was whether by continuing the treatment with this object in view the condition of standstill could be maintained in a number of cases for a considerable time. The author had found that it could be maintained for four months and a half, but it seemed not improbable that it could be maintained longer, and of course the longer it was maintained the greater the probability that the tubercle bacilli would die out, and the improvement become permanent. With regard to the value of tuberculin in surgical practice Mr. Cheyne said he had arrived at the following provisional conclusions:

That in cases of intractable lupus it was of great value when combined with other measures. In cases of tubercular glands it hardly repaid the trouble and inconvenience, except in so far as it might reduce the periadenitis, and thus pave the way for operative measures. In diseases of joints its place could as yet hardly be settled, but it was best not to employ it in the early stages, but to reserve it as a means, after operation, of aiding the prompt healing of the wound; it might be of value in enabling the surgeon to perform less severe and radical operations than he might otherwise do. In cases of bone disease it would probably only be useful after operation. In genito-urinary tuberculosis it could seldom come into play—one reason being the great frequency with which these diseases were combined with sepsis. In tubercular laryngitis it appeared to be of use in certain cases. While admitting the small value which could be attached to his opinion as regarded phthisis, Mr. Cheyne said he could not but think that the dangers of Koch's treatment in that disease had been unduly magnified and its benefits unduly decried. The discussion on Mr. Cheyne's communication was deferred to a meeting of the Society to be held next week.

The question as to the extension of the medical curriculum is one which involves many difficulties in the settlement of details. At a meeting held on April 30th, the College of Physicians (or rather the Fellows thereof, for Members have no voice) formally approved of the curriculum being lengthened to five years, but how the extra year is to be spent by the student is a point reserved for further consideration. Many of those interested in medical education urge that any reform should begin at the bottom, and that the standard of the preliminary examination in the subjects of general education should be raised considerably. This, however, is a matter with which neither the College of Physicians nor the College of Sur-

geons has the power to deal, but only the General Medical Council.

The Government has abandoned the proposal to abolish the posts of certifying factory surgeons.

A strong opposition to the new scheme for the reconstruction of the London University is being organized among the members of Convocation.

VARIOLA ON THE SCOTIA.

To the Editor of the Medical Record.

It was a surprise to notice in the *London Lancet* of a recent date a communication from Dr. Barnett, late surgeon of the steamship Scotia, giving his experience recently at the New York Quarantine. It was the impression here that the least said about the doctor's management of the cases referred to by him, the better it would be for his reputation.

The facts are these, as shown by the following report to me by Deputy Health Officer E. C. Skinner; and except so far as they relate to the deputy's personal interco urse with Dr. Barnett, they are confirmed by the personal observation of the undersigned.

The steamer Scotia arrived at Quarantine, February 8, 1891, from Mediterranean ports, with a case of variola discreta among the immigrants, which was discovered while inspecting them. At Palermo, on January 11th, four hundred and eighty-four Italians embarked; among them one Storella Pasquale, who was the victim of the dis ease mentioned. This man was vaccinated by the Scotia's doctor January 23d. Three days later (January 26th) the man developed an eruption. This eruption, thirteen days later, on arrival at this Quarantine, was distinct on all parts of the body, including the palmar and plantar surfaces, although many of the crusts had exfoliated, the disease evidently being modified by vaccination in childhood. Dr. Barnett, the surgeon of the Scotia, claimed it was a case of *vaccinia*.

The doctor failed to show how it was possible that such an eruption as this man had could be the result of a vaccination made three days previously. Dr. Barnett's attempt to cover his ignorance of the character of the disease by a tirade of abuse of the Deputy Health Officer, as reported by him, and his talk of having an "investigation," induced the Health Officer to request an opinion from the physicians of the New York Contagion Hospital, to which the patient was removed. The following certificate of diagnosis was given:

"February 11, 1891.

"We, the undersigned, hereby certify that the case of Storella Pasquale, aged about twenty-five years, an Italian immigrant from the steamship Scotia, was examined at Reception Hospital, February 9, 1891, having been brought there by the Health Officer of the Port, and we find that the case is variola discreta, or varioloid, about the fourteenth day of its development, the pustules having dried down and in most part exfoliated.

"This diagnosis cannot be questioned.

"F. W. Lester, M.D.,
Resident Physician Willard Parker Hospital.
"F. H. Dillingham, M.D.,
Inspector Contagious Diseases."

Subsequently to the removal of the case of small-pox to hospital, and while the steamer was being disinfected, the Health Officer took occasion to express to the captain of the Scotia his regret for the necessity for the detention of his steamer. Captain Crockhart replied, "Oh, well, there are two other cases among the passengers just like the one sent to hospital." This remark indicated that either the medical officer who inspected the passengers was at fault in not discovering the cases, or that the captain concurred with the doctor in his belief that the case removed was not small-pox.

The two cases referred to, and which Dr. Barnett asserted were typical cases of secondary vaccination, were therefore taken from the steamer and sent to the New York City Reception Hospital for Contagious Diseases, with a request that a certificate of diagnosis should be sent to the Health Officer.

The following certificates were the result:

"February 11, 1891.

"We, the undersigned, hereby certify that the case of Salvatore Elia, aged about ten years, was examined by us this day at Reception Hospital, where he was brought by Dr. William M. Smith from the steamship Scotia, is one of pediculosis, the eruption having been caused by these parasites. There is no evidence of variola, eruptive *vaccinia*, or other eruptive disease.

"Cyrus Edson, M.D.,
Chief Inspector Health Department.
"F. H. Dillingham, M.D.,
Inspector Contagious Diseases.
"F. W. Lester, M.D.,
Resident Physician Willard Parker Hospital."

"February 11, 1891.

"We, the undersigned, hereby certify that Maria Lajora was brought to Reception Hospital from the steamer Scotia by Dr. William M. Smith, and examined by us. We find her suffering from eczema, due to vermin, and self-vaccination from the vaccinal sores from previous vaccination.

"There is no evidence of variola or other eruptive disease.

"Cyrus Edson, M.D.,
Chief Inspector Health Department.
"F. H. Dillingham, M.D.,
Inspector Contagious Diseases.
"F. W. Lester, M.D.,
Resident Physician Willard Parker Hospital."

The Scotia was thoroughly disinfected in every steerage by sulphurous acid gas, particular attention being given to the one occupied by Pasquale Storella, as thoroughly as hundreds of other steamers that had small-pox on arrival at this Quarantine, and from which, in not a single instance, has the contagion of the disease been communicated after being disinfected.

The ignorance, inexperience, carelessness, or neglect of some of the medical officers of passenger steamers is the occasion of infinite vexation and anxiety to Quarantine officials, and of delay and expense to passenger steamship companies.

William M. Smith, M.D.,
Health Officer Port of New York.

Health Officer's Department, State of New York,
Quarantine, S. I., May 11, 1891.

HOW LAWSON TAIT DOES A SUPRA-PUBIC CYSTOTOMY.

To the Editor of the Medical Record.

Sir: I have recently had the pleasure of seeing Mr. Tait do a supra-pubic cystotomy for stone in the bladder which was of peculiar interest from the difficulty of the case, and from the, to me, unique method of operating. The patient, a man well up in years, was very stout, weighing I should think three hundred pounds, with an abdominal wall fully five inches thick over the bladder, which rendered the operation exceedingly difficult. This difficulty, however, seemed to rather please the fancy of the operator than otherwise.

The patient being under the anæsthetic, all rules laid down by other surgeons in this operation were ignored by Mr. Tait as unnecessary and a waste of time.

With no rectal bag in rectum, no fluid in the bladder to distend it and push up the peritoneum, and not even a sound in the bladder as a guide, he cut rapidly down through the abdominal wall to muscle, on reaching which he divided the tendon transversely, closely hugging the pubic arch to avoid the peritoneum, and with a finger in the wound

felt for and found the viscus. Without waiting to sponge away blood, he caught up the wall of the bladder with a couple of pairs of long forceps, and between them opened into it with the point of a scalpel in the same way as he would the peritoneum in abdominal section. Then with a finger in the bladder he explored it, and passing in a pair of placental forceps caught and dragged out a stone measuring two inches by one and one-half inch.

He completed the operation by introducing an abdominal glass drainage-tube to the floor of the bladder, partially closing the bladder-wound by a suture above and below the tube, and the external wound by a few sutures on each side of the tube. The whole operation from start to finish did not last ten minutes. H. MEEK, M.D.

LONDON, ONTARIO.

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from May 10, 1891, to May 16, 1891.

PATOZKI, JULIUS H., Major and Surgeon. By direction of the Acting Secretary of War, par. 5, S. O. No. 24, January 29, 1891, from this office, granting six months leave of absence, is so amended as to grant said leave on surgeon's certificate of disability. S. O. 99, par. 15, A. G. O., May 1, 1891.

CLARKE, JOSEPH T., First Lieutenant and Assistant Surgeon. Relieved from duty at Fort Riley, Kan., and will report in person to the commanding officer at Camp Poplar River, for duty at that station, relieving First Lieutenant Jefferson D. Poindexter, Assistant Surgeon. S. O. 102, par. 14, A. G. O., Washington, D. C., May 5, 1891.

POINDEXTER, JEFFERSON D., First Lieutenant and Assistant Surgeon. On being relieved by Lieutenant Clarke, will report in person to the commanding officer at Fort Niobrara, Neb., for duty at that post. S. O. 102, par. 14, A. G. O., Washington, D. C., May 5, 1891.

MCCAW, WALTER D., Captain and Assistant Surgeon. Relieved from duty at Fort McPherson, Ga., and will report in person to the commanding officer at Camp Pilot Butte, Wyo., for duty at that post, relieving Captain George E. Bushnell, Assistant Surgeon. S. O. 102, par. 14, A. G. O., Washington, D. C., May 5, 1891.

BUSHNELL, GEORGE E., Captain and Assistant Surgeon. On being relieved by Captain McCaw, will report in person to the commanding officer at Fort McKinney, Wyo., for duty at that post. S. O. 102, par. 14, A. G. O., Washington, D. C., May 5, 1891.

EDIE, GUY L., Captain and Assistant Surgeon. Relieved from duty at Fort Douglass, Utah Ter., and will report in person to the commanding officer at Fort Niobrara, Neb., for duty at that post, relieving Major Timothy E. Wilcox, Surgeon. S. O. 102, par. 14, A. G. O., Washington, D. C., May 5, 1891.

WILCOX, TIMOTHY E., Major and Surgeon. On being relieved by Captain Edie, will report in person to the commanding officer at Fort Huachuca, Ariz. Ter., for duty at that post. S. O. 102, par. 14, A. G. O., Washington, D. C., May 5, 1891.

CABELL, JULIAN M., First Lieutenant and Assistant Surgeon. Relieved from duty at Fort Niobrara, Neb., and will report in person to the commanding officer at Fort Buford, N. Dak., for duty at that post, relieving Major Valery Havard, Surgeon. S. O. 102, par. 14, A. G. O., Washington, D. C., May 5, 1891.

HAVARD, VALERY, Major and Surgeon. On being relieved by Lieutenant Cabell, will report in person to the commanding officer at Fort D. A. Russell, Wyo., for duty at that post. S. O. 102, par. 14, A. G. O., Washington, D. C., May 5, 1891.

GIRARD, JOSEPH B., Major and Surgeon. Relieved from duty at Alcatraz Island, Cal., and will report in person to the commanding officer at Benicia Barracks, Cal., for duty as post surgeon at that post, and attending surgeon at Benicia Arsenal, Cal., relieving Major John H. Janeway, Surgeon. S. O. 102, par. 14, A. G. O., Washington, D. C., May 5, 1891.

JANEWAY, JOHN H., Major and Surgeon. On being relieved by Major Girard, will repair to Philadelphia, Pa., and assume the duties of Attending Surgeon and Examiner of Recruits in that city, and in addition to his duties at Philadelphia, will perform the duties of Post Surgeon at Frankfort Arsenal, Pa. S. O. 102, par. 14, A. G. O., Washington, D. C., May 5. 1891.

LAGARDE, LOUIS A., Captain and Assistant Surgeon. Relieved from duty at Fort Assiniboine, Mont., and will report in person to the commanding officer at Fort McHenry, Md., for duty at that post, relieving Major Charles B. Byrne, Surgeon. S. O. 102, par. 14, A. G. O., Washington, D. C., May 5, 1891.

BYRNE, CHARLES B., Major and Surgeon. On being relieved by Captain LaGarde, will report in person to the commanding officer at Fort Assiniboine, Mont., for duty at that post. S. O. 102, par. 14, A. G. O., Washington, D. C., May 5, 1891.

KENDALL, WILLIAM P., Captain and Assistant Surgeon. Relieved from duty at Fort D. A. Russell, Wyo., and will report in person to the commanding officer at Fort Douglass, Utah Ter., for duty at that post. S. O. 102, par. 14, A. G. O., Washington, D. C., May 5, 1891.

MCKEE, JAMES C., Lieutenant-Colonel and Surgeon. Having been found incapacitated for active service by an Army Retiring Board, is, by direction of the Acting Secretary of War, granted leave of absence until further orders, on account of disability. S. O. 106, par. 11, A. G. O., Washington, D. C., May 9, 1891.

BIRMINGHAM, HENRY P., Captain and Assistant Surgeon. By direction of the Acting Secretary of War, the extension of ordinary leave of absence granted in S. O. 81, A. G. O., April 10, 1891, from this office, is changed to leave of absence on account of sickness, to date from May 1, 1891. S. O. 108, par. 4, A. G. O., Washington, D. C., May 12, 1891.

BACHE, DALLAS, Lieutenant-Colonel and Surgeon. By direction of the Acting Secretary of War, is relieved from duty as a member of the Army Medical Examining Board, New York City, and will return to his proper station, Omaha, Neb., and resume his duties as Medical Director, Department of the Platte. S. O. 108, par. 5, A. G. O., Washington, D. C., May 12, 1891.

Official List of Changes in the Medical Corps of the United States Navy for the week ending May 16, 1891.

BRADLEY, G. P., Surgeon. Detached from the Mohican and placed on waiting orders.

WALTON, T. C., Medical Inspector. Ordered to Naval Academy, to examine applicants physically for admission.

BRIGHT, GEORGE A., Surgeon. Ordered to Naval Academy, to examine applicants physically for admission.

STEELE, J. M., Passed Assistant Surgeon. Ordered to Naval Academy, to examine applicants physically for admission.

DICKSON, S. H., Surgeon. Ordered to the Constellation.

RUSH, WILLIAM H., Passed Assistant Surgeon. Detached from the Saratoga, and ordered to await duty to sea.

ATLEE, S. W., Passed Assistant Surgeon. Detached from Navy Yard, League Island, and ordered to the Saratoga.

Brownell, C. De W., Assistant Surgeon. Ordered to Navy Yard, League Island.

Streets, T. H., Surgeon. Detached from Naval Examining Board, and ordered to prepare for sea.

Mackie, B. S., Surgeon. Ordered as member of Naval Examining Board.

Curtis, L. W., Passed Assistant Surgeon. Detached from Naval Academy, and ordered to the Practice Ship Constellation.

Leach, Philip, Passed Assistant Surgeon. Orders to Practice Ship Constellation revoked.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending May 16, 1891.

	Cases.	Deaths.
Typhus fever	1	0
Typhoid fever	18	5
Scarlet fever	241	34
Cerebro-spinal meningitis	3	3
Measles	392	22
Diphtheria	90	21
Small-pox	0	0
Varicella	2	0
Pertussis	1	11
Erysipelas	0	0
Mumps	1	0
Rötheln	0	0

Malaria is said to be unknown in New Zealand.

Obligatory Vaccination.—The Paris Academy of Medicine has been engaged for some time in a discussion of the question of obligatory vaccination in France, the general opinion being that, in spite of some disadvantages, the measure would be productive of good.

Salol in Typhoid Fever.—Dr. Frank P. Wilson, writing in the *Southern Clinic* for March, 1891, says that he has found salol to be a very unsatisfactory remedy in rheumatism, but that in infantile diarrhœa he has found its administration attended with very good results. The use of one grain of the drug every four hours promptly checked the diarrhœa, and the continued administration of the remedy two or three times a day for a few days effectually prevented a relapse. In typhoid fever he had had very favorable results, and in all cases in which he had given it from the onset of the disease there was no tympanites, no diarrhœa, no dry tongue, nor sordes on the teeth. Even when the treatment was begun late in the course of the disease, when the symptoms were already grave, the whole condition was changed for the better within two days by two- or three-grain doses of salol every four hours. He did not believe that the duration of the fever was shortened at all, but all the symptoms were ameliorated, delirium was kept away, and the patient preserved a desire for food, usually waiting anxiously for the milk hour to come around. One grain of salol was given every four to six hours, except when there was severe diarrhœa, when the dose was doubled for a short time.

The Dose of Tuberculin.—At the Moabit Hospital in Berlin, treatment with Koch's fluid was commonly commenced with a dose of one milligramme, but latterly one-tenth of a milligramme only has been used in many cases, and increased by one-tenth of a milligramme a day for ten days, then by two-tenths every other day, until the amount has reached two or three milligrammes, when the increase is made half a milligramme.

Who Discovered the Comma-bacillus?—Dr. Brittan, who died a few weeks ago in London, claimed to be the discoverer of the comma-bacillus, and was endeavoring to establish his right to be so regarded by the world. Concerning his claims, Dr. J. Mortimer Granville wrote to the *Times* as follows: "I have just come from the death-chamber of the real discoverer of the comma-bacillus of cholera, a discovery which Professor Koch has since arrogated to himself, not hesitating to call it by his own name as the 'Koch comma-bacillus.' . . . Dr. Brittan only a few days ago placed the original papers in my hands for his vindication, he having come to London partly for that purpose. This afternoon I was summoned to find him dead, being stricken down with heart disease on the stairs of the house where he was lodging. It is too late now to do him justice; but there are some, at least, still living who worked with him in the old days, and who will not fail to honor the memory of a physician who was not only an expert of rare ability in microscopy, as applied to the investigation of disease, when that enterprise was in its infancy, but who was, in a very practical sense, the father of the whole bacteriological system, and, as such, the pioneer of a work which has not yet done more than show a little of its vast capability in the health-service of humanity."

The Man that will give to the world an unfailing remedy for sprains shall have his name writ high upon the wall of the temple of fame, and his praises shall be sung through long ages by the bards of a grateful humanity.

OPIATES IN ACUTE PERITONITIS.

BY STEPHEN SMITH, A.M., M.D.,

NEW YORK.

PROFESSOR ALONZO CLARK, in his article on "Peritonitis," in "A System of Practical Medicine," makes the following statement: "In 1840 there was a very fatal visitation of puerperal fever in this (Bellevue) Hospital. . . . I was a daily visitant and took notes of all the cases. . . . The disease was fearfully fatal, although every known mode of treatment was tried in different cases. . . . But all, with one or two exceptions, with the same result. At this time the opium plan was on its trial, and I had not acquired a confidence in it that authorized me to try it in these cases. The time for it came in 1851. Then a sudden, vigorous attack occurred. One woman was sent to me in whom the disease was well advanced. I instructed my house physician, not how much opium to give, but what effects to produce by it. I found this woman dying next day, and that she had taken only three grains of opium in three doses. In three or four days, seven cases were sent to me from the lying-in-wards. One was returned for error in diagnosis, and six put under treatment. Having found that prudence was so much more conspicuous in my house physician than courage, another house officer, who combined them both, was selected to be in almost constant attendance. The instructions were in these words: 'I want you to narcotize those women to within an inch of their lives.' He did it, and saved every one of them. This gentleman is now known over the whole land as a learned and distinguished surgeon. I feel called upon to give his name in this connection that he may be a witness to the facts I state, and for the admiration with which his nerve and prudence impressed me."

It is an interesting fact that Professor Clark failed to give the name of the gentleman he so highly complimented, and whom he thus publicly called to witness to the truth of his statement. As I was then a resident student in Bellevue Hospital, and had the care of the six cases to which he alludes, I assume that I am the person referred to, and will take this occasion to witness to the facts Professor Clark brought forward in his paper.

At the period mentioned by Professor Clark Bellevue was a hospital in name only. The buildings were erected in the early part of the century—1811–16 for prison and alms-house purposes. They were chiefly built on ground reclaimed from the river, and without underdrainage or sewerage. The buildings were very massive in construction, and in the prison style of that day, without pretence of ventilation. For a quarter of a century Bellevue was little else than a prison or a pest-house. All forms of contagious and infectious diseases were received into its crowded and illy ventilated wards. At various times yellow fever, typhus, and typhoid fevers, small-pox and cholera have been the prevailing diseases of its inmates.

The evolution of this establishment into a hospital was a very slow process. The prisoners were first removed to the Island, and gradually all the able-bodied paupers were provided with quarters in the new alms-house. In time only the sick poor were detained at Bellevue, and the institution assumed the general aspect and character of a hospital. In 1840, the date to which Professor Clark alludes, the hospital had a resident physician who was the sole authority in managing its general and medical affairs. The appointment was purely political, and the government was of the same character. In 1846–7 there came a complete change in the administration of the institution by the selection of a competent medical board, and the final retirement of the resident physician. At this latter date Bellevue, as an organized hospital, had its origin.

There was, however, comparatively little improvement in the sanitary condition of the hospital buildings for many years. Gradually, better ventilation was secured and the general cleanliness of the wards and beds was improved.

The maternity wards of Bellevue were at this early date in the same condition as the other wards. They were not specially separated from the other wards except that they were situated at the extreme end of one of the wings. The number of confinements averaged one daily, usually, though they occasionally reached the number of sixty in a month.

Puerperal fever was the great scourge of the hospital at that period. Whenever it appeared nothing seemed to control its progress and no treatment saved its victims from a speedy death. These facts are confirmed by referring to the outbreak in 1840, alluded to by Professor Clark, and reported by Dr. Vaché, the resident physician. The latter states that "the disease made its appearance on January 12, 1840, and was quickly followed by two more cases apparently so malignant that it was immediately determined to vacate the room with a view to its purification. The inmates were accordingly removed and the apartment, whitewashed, ventilated, and scrubbed; the bedsteads were cleansed; new beds and bedding introduced, and at the expiration of about a week it was considered sufficiently disinfected to return to it in safety. But the disease immediately reappeared equally as violent and irremediable as before, and it was concluded most judicious to abandon the building. As promptly as it could be accomplished, another, some distance from the almshouse, and appropriated for a nursery, was put in the most perfect order, the bedsteads were cleansed and painted; new beds and bedding were furnished; the physician and nurse were changed; the pregnant women were directed to cleanse their persons by bathing, new clothes, even shoes, were given to them immediately previous to transferring them to their new habitation, and all intercourse arrested with the inmates of the surrounding premises. Notwithstanding these precautions, the first woman confined and subsequently four others in succession out of five labors were attacked with the disease, and in every case it was fatal. A further effort in the cause of human life, and as the only rational means of arresting this terrible scourge was the total abandonment of the lying-in establishment at Bellevue; this was done without delay."

To the earlier resident medical students at Bellevue Hospital this sketch presents a graphic but familiar picture of an outbreak of puerperal fever in the years 1840–51. Cleanliness and isolation of patient and physician

[1] Address before the Fifth, or Southern, District Medical Association, held in Brooklyn, N. Y., May 26, 1891.

were the chief preventive measures employed, but they were powerless to control the spread of the disease.

The mortality reported by Vaché was appalling. Of 21 cases. 19, or over ninety per cent., proved fatal. Nor was this death-rate unusual, as we learn from other sources.

It is important to notice the pathological conditions which were found to exist in the fatal cases. Careful autopsies were made in 17 of these cases. The records of these autopsies, as published by Dr. Vaché, were made by Professor Clark, for he states that he was a daily visitor and took notes of all the cases; and that it was from these notes that Vaché compiled his report of the epidemic.

In 16 of the 17 cases examined post mortem there was, according to these notes, peritonitis. In these cases there was effusion into the peritoneal cavity, which is variously described as "sero-purulent" and "sero-lymphatic." In 17, or all of the cases, the uterus was examined, and the pathological changes reported. In two cases this organ appeared to be without any special change. In the remaining cases the alterations were those due, apparently, to metritis. In several there were putrefactive changes of matters within the cavity, as the remains of the placenta and the natural discharges after child-birth. The following is an example: "The cavity of the uterus was covered over, from the fundus down to the cervix, with a dark, chocolate, stringy, fetid substance which was easily scraped off with a knife, showing the surface beneath injected; the cervix was covered with a firmly adherent substance, of a greenish-gray color, with spots of white; the os uteri was of a dark purple color: beneath the peritoneal surface of the uterus there was much lymph deposited."

In several instances pus was found in the ovaries and fallopian tubes. Pus was also found in considerable quantity between the uterus and bladder. In one case many peritoneal bands had formed, binding the viscera together; an abscess four inches in diameter separated the peritoneum from the walls of the abdomen; the sub-peritoneal cellular tissue of the pelvis and extending nearly to the kidney resembled lint soaked in pus; numerous deposits of pus were found under the peritoneal covering of the uterus, in the broad ligaments, ovaries, and fallopian tubes; the left internal iliac vein was closed by a firm clot which extended into the gluteal, ischiatic, and obturator branches, and in the clot were found collections of pus."

The records of these autopsies were more or less accurately repeated on every recurrence of puerperal fever at Bellevue Hospital between the years 1840–1851. They undoubtedly may be taken as illustrating the ordinary form of puerperal peritonitis, when that disease prevailed in this hospital.

It is important, also, to notice the treatment of these cases, which is given in considerable detail. Of the two cases which recovered, the principal treatment in one was saline cathartics, wet cups to the abdomen, and opiates; and in the other venesection and leeches to the abdomen. Of the fatal cases, four were treated with saline cathartics and venesection, chiefly; in eight, calomel in scruple doses was given, combined with venesection and leeches; in ten, venesection was the more important feature in the treatment, combined in five cases with leeches; in five cases turpentine, as a cathartic, was largely employed. In one, large doses of cinchona bark were used, as recommended by Dr. Burns, and later, turpentine as a purgative.

It will be seen that the treatment was so mixed that it would be difficult to draw any conclusions as to the efficiency, or rather inefficiency, of any one remedy. Still it is noticeable that purgatives were actively and efficiently employed in seventeen of the twenty-one cases, and that in five cases the cathartic was salts. In the other cases, calomel and turpentine, two approved antiseptic remedies, were administered freely. Opiates in the form of opium and Dover's powder were given in most cases, but in small and occasional quantities.

This review of the outbreak of puerperal fever in 1840 may be regarded as fairly illustrating the average features of the recurring appearances of the scourge in the lying-in wards of Bellevue Hospital, prior to the year 1851. Professor Clark truly says: "Up to the time when the opium treatment was adopted peritonitis was a fearful word; a large proportion of those attacked by it, died of it."

I was one of the resident staff of surgeons of Bellevue Hospital in 1851, and well remember the excitement created when the first case of puerperal fever was announced. To the visiting staff it meant a hopeless struggle with a violent pestilence, and to the resident staff the loss of the obstetric service, which was highly prized. Professor Clark had already in his lectures, and especially in the Pathological Society, advanced the opinion that opium might prove to be a successful remedy in peritonitis. He related his experience in cases which he saw in consultation with physicians in Vermont, where he lectured during the autumn months. He says, in regard to his experience: "I found that they were treating the disease on the Armstrong plan; that is, bleeding freely, and then administering a full dose of opium, as they said, 'to prolong the effects of the bleeding.' In most cases there was a second bleeding and a second administration of opium. I found they were getting better results than we were in New York, and I studied their cases as closely as I could, and reached the conclusion that opium was the curative agent, and that it would be safe to omit the abstraction of blood. The conviction grew in strength with every new case and I saw several cases with different physicians. . . . The idea then formed was, that to establish the narcotic effects of opium within safe limits, and continue them by repeated administration of the dose, would cure uncomplicated peritonitis; that a kind of saturation of the system with opium would be inconsistent with the progress of the inflammation, and would subdue it. There was no theory to build the treatment upon, and no explanation of the action of the drug, in my mind. What I saw of the action of two doses of opium was the only foundation for the idea."

The first case of puerperal fever in the outbreak of 1851, in Bellevue, resembled in all its peculiarities those of previous epidemics. The onset was violent, the symptoms characteristic and the termination rapidly fatal. The patient was early transferred to Professor Clark's ward and there were great anticipations of the success of the opium treatment. The uninterrupted progress of the disease to its fatal termination, in spite of the opium administered, produced a very unfavorable impression upon the visiting physicians as to the alleged value of this remedy. Professor Clark declared, however, that the opium had not been fairly tested, for it was found that the drug had been given in such very small quantities that no such effects could have been obtained as he intended or desired.[1]

Three new cases were soon after transferred to Professor Clark's care; then two more and then one, making in all six. They occupied a separate ward and Professor Clark determined to make a thorough test of the opium treatment. Special nurses were provided and I was selected as the immediate medical attendant. His instructions were very explicit. He required that I should aim to see the patients every hour; should closely watch the pulse and respiration, and personally see that the medicine was regularly given. In regard to the opium, he stated that I must not be governed at all by the amount administered, but by the effects produced. The condition of the patient to be secured was that of semi-

[1] "The drug symptoms to be produced," Professor Clark says, "are subsidence or marked diminution of the pain; some or considerable tendency to sleep; contraction of the pupils; reduction of the breathing to twelve respirations in the minute; in the favorable cases, a considerable reduction in the frequency of the pulse; a gentle perspiration; an itchy state of the skin and oftener of the nose; absolute inactivity of the bowels; and after a time, a subsidence of the tumor and tenderness in them; some suffusion of the eyes."

narcotism; this was to be determined by the degree of stupor and the respiration; the patient must require to be shaken to be aroused to consciousness; and the respiration might fall to twelve per minute, but not below that figure. In concluding his instructions he inquired if I had ever heard the school-master say, "I will whip you within an inch of your life." And being assured that I was familiar with the expression and its significance, he said, "I wish you to give these patients opium to within an inch of their lives."[1]

The treatment was immediately begun. The opiates were given in the form of morphine, solid opium, and laudanum, but the quantity of each was accurately determined by the apothecary and estimated in grains of opium. At the outset each patient received one grain of opium every hour, for three doses. No effect being perceptible, the dose was increased to two grains every hour and continued for three doses. Failing with this dosage, the opium was increased to three grains every hour. In four cases this amount of opium had the desired effect, and it was continued in that amount. In the remaining cases, it had to be increased to four grains every hour. One of these remaining cases yielded to this amount, and the opiate was continued at that rate. The other, or sixth case, was much more obstinate, and the opium was steadily increased until the dose reached twelve grains every hour. This amount simply secured a light but continuous sleep, from which she readily awoke on placing the hand upon her wrist to examine her pulse.

The first four cases continued to receive three grains of opium every hour for three or four days, when the pulse fell to its normal standard, the tympanites subsided, the tenderness of the abdomen disappeared, and the patients were evidently convalescent. The opium was discontinued. They rapidly recovered and remained well.

In the fifth case an episode occurred, which Professor Clark mentions, but not accurately. The patient was a tall young woman, having a pale and somewhat cadaverous face. On the fourth night, while the four-grain doses of opium were being given, the nurse failed to wake me at the usual hour and I overslept two hours. On awakening and noticing the time that had elapsed, I hastened to the ward. The nurse was sleeping soundly in her chair. The patients were all sleeping heavily and apparently doing well, except the fifth. On approaching her bedside, I was struck with her death-like pallor, heightened by the feeble light of a candle, on an opposite shelf; her half opened eyes; her fallen jaw, and the absence of pulse. I stood a moment quite paralyzed at the thought of my neglect, and that of the nurse, when I noticed that she gasped. There was an interval, and then another gasp. I counted these efforts at respiration, and found that the fourth occurred just after the minute had expired.[2]

I at once roused the nurse, and took active measures to recover the patient from her profound narcotism. After several hours continuous effort, she was regarded as securely restored. All the symptoms of peritonitis now rapidly subsided; the pulse had falled from 112 to 92 per minute; the tympanites and tenderness had disappeared, and she expressed herself as feeling well. Within twenty-four hours all the evidences of peritonitis recurred, and the treatment was renewed, three grains of opium being given instead of four. Semi-narcotism was readily produced, and after a brief period the symptoms again subsided, the treatment was suspended and she was permanently cured.[1]

The sixth case proved an anomaly in tolerance of opiates. During twelve days the treatment was persevered in, the pulse remaining at about 120; the respirations 34 to 36; the abdomen greatly distended and tender to the touch; lancinating pains; the features pinched; perspiration at intervals, etc. During these twelve days this patient took the equivalent of 1,950 grains of opium and she neither vomited during that time nor had she an evacuation of her bowels.[2] At no time was she so narcotised that she would not awaken when any one placed his hand on her wrist. She remained in the hospital as an assistant in the laundry for six months after her recovery, and during that time she was in excellent health.[3]

[1] The following notes of one of these cases contributed by Professor Clark to Keating's edition of Ramsbotham's System of Obstetries illustrates the symptoms and progress of the disease while under treatment, and will prove instructive to those unfamiliar with this method of medication:

A. H——, aged twenty, married, delivered of her first child October 1, 1851. The labor was natural and of the usual duration; convalescence was not attended by any untoward symptoms except a slight diarrhœa. . . . On the tenth day after confinement she was seized with a chill at 10 A.M.; chill lasted an hour; the abdomen was markedly tympanitic and extremely tender, and the seat of lancinating pains which caused sobbing; pulse 120; respiration thoracic; tongue clear. Ordered solution sulph. morph. (gr. xvi., to aquæ, ʒj.), ♏. x. every hour. She slept most of the day and succeeding night quietly, but not profoundly.

Second day, 10 o'clock.—Tympanites increased; tenderness somewhat diminished; extreme thirst; occasional vomiting of a bright green fluid; bowels quiet; lochia had ceased previous to attack; pulse, 120; other symptoms as before. It was obvious that not much impression had been made upon the disease in the first twenty-four hours, and the solution was given ♏. x. every half hour. This produced sleep, and by evening the pulse had fallen to 90.

Third day.—Tympanites and thirst continued; retention of urine; intellect rather obtuse; other symptoms as before. The morphine solution was now increased to ♏. xxx. every hour. Those doses were continued from noon to six or seven o'clock in the evening, when the signs of narcotism became rather alarming. She slept heavily; was roused with difficulty; would not reply to questions; pupil contracted almost to a point; pulse 68, and respiration 7 in the minute. The opiate was suspended and tablespoonful doses of coffee administered. The narcotism continued for six or seven hours, and gradually subsided.

Fourth day.—Tympanites diminished; tenderness markedly less; features composed; intellect rather dull; pulse 78; tongue dry in the centre; green vomiting occasionally; slight hysterical symptoms; respiration 15; morphine solution resumed, ♏. x. every half hour. Narcotism recurred at about the same hour as last evening, in which the sleep was very profound; and the respiration only 5 in a minute. Treatment as on the previous evening. Toward morning these unpleasant effects of the medicine passed off.

Fifth day.—The tongue was dry and slightly brown, but patient declares that she feels quite well; tympanites has nearly disappeared; no pain or tenderness; pulse 80; respiration 15; some appetite. . . . At 11 A.M. morphine solution resumed, ♏. x. every two hours. At night wakefulness and pain in the abdomen; opium, gr. iij. every hour, under the influence of which she slept quietly.

Sixth day.—Sleeps most of the time; easily aroused, but answers questions slowly and with an effort; tongue moist and not furred; tenderness that recurred last night less; pulse 80; still vomits green fluid; treatment continued.

Seventh day.—Symptoms all improved; opium, gr. j. every hour.

Eighth day.—Abdomen soft and free from pain or tenderness; thirst slight, says "I feel so much better;" was decidedly convalescent. From this time the opium was continued in gradually diminished doses. The bowels were not opened until the thirteenth day. After this treatment was continued a few days she was discharged in her usual health.

[2] No effort was made to secure an evacuation of the bowels during the opium treatment. Professor Clark says: "Purgatives are entirely inadmissible. The bowels should be left entirely at rest till they recover their muscular tone; then they will expel, first the gas and then the fæces; or if, after the inflammation is subsided, they do not move of their own accord, injections are admissible. I have often left the bowels inactive for fourteen days without any recognizable consequences."

[3] The following extracts from the records show the course of treatment of this patient. Treatment was commenced at 10 A.M. with 2 grains of opium hourly; at 2 P.M. dose increased to 4 grains; at 3 P.M. gr. iv.; at 4. gr. v.; at 6. gr. viij.; at 8. gr x., at 9. gr. xij.; at 11, sol. morph. sulph. ʒiss., at 12. ʒj., at 1.30 A.M. (respiration 6), 0; at 6 A.M. (respiration 12), opium gr. xij.; at 10 A.M., sol. ʒj.; at 12 M. ʒij.; at 1 30 sol ʒij.; at 2.30. ʒij; at 3.30, opium, xxiv. gr.; at 5. ʒij.; at 6.30, sol. ʒijss.; at 7.30, ʒij.; at 9, opium gr. xiv; at 10, gr. xvj., at 11. gr. viij.; at 1 A.M., sol. ʒiss.; at 2, ʒiv.; at 3.15, opium gr. xx.; at 4. ʒiiss.; at 5, ʒij; at 6, ʒiiss., at 6.30, opium gr. x.; at 7, sol. ʒiiiss.; at 8, opium gr. xxij., at 9.30, sol. ʒiv.; at 10, ʒiij.; at 11.30. ʒiij., at 12, o. On one day she took the equivalent of 472 grains of opium.

[1] Professor Clark thus describes the method of medication: "The plan is to begin with a dose that is safe, say two or three grains of opium or its equivalent of sulphate of morphia and in two hours notice its effect. If any of the opium symptoms have appeared, repeat the dose; if none, increase by one grain, and so on at intervals of two hours till the degree of tolerance in the patient is ascertained. After that the case can be treated by a diminished occupation of the physician's time, two or three visits a day. The dose is to be increased if the opium symptoms diminish, or discontinued if narcotism is approaching. The duration of the treatment will be sometimes no more than two or three days; it may be a week or even a fortnight, and in one case the symptoms persisted mildly for forty days, and then yielded. In this case the medicine used was sulphate of morphia and the enormous dose reached, by steady and gradual increase, was one grain and a quarter every forty minutes in a boy ten years old."

[2] Alluding to this subject, Professor Clark says: "Of these several signs of opiumism there is none more valuable than the frequency of the respiration; and while the physician aims to reduce it to twelve in a minute, there are chances that he will see it fall to something below that. I have often counted it at seven, and in perhaps two cases it fell to seven in two minutes; and yet these cases of marked oppression from opium all recovered."

The recovery of these six consecutive cases naturally produced a profound impression upon the resident and visiting physicians of Bellevue. As the cases were typical of those ordinarily occurring in that hospital and as opiates were the sole remedies used in their treatment, it was apparent that a new era in the therapeutics of that scourge had begun.

From this time forward opium continued for twenty years to be the chief remedy employed in peritonitis in Bellevue Hospital, with satisfactory results. Opium in peritonitis came into use generally in the city. Professor Clark states "that in private practice the drug has been perhaps more curative than in the hospital."

It is apparent from the preceding review that, previously to the introduction of the opium treatment, puerperal peritonitis was a most destructive disease in Bellevue Hospital when treated by the methods employed prior to 1851. With the introduction of opium, employed as the chief remedy, and in the manner directed by Professor Clark, the same disease, occurring under the same circumstances, became so manageable, that a mortality of ninety per cent. was reduced certainly fifty per cent. These facts lead inevitably to the conclusion that the opium treatment has a place in the therapeutics of that affection of no small importance. Precisely what that position is, it is, perhaps, impossible now to state.

Professor Clark remarks that he cannot explain the curative action of opium in peritonitis. Professor Fordyce Barker, who has had a large and varied experience in puerperal peritonitis in Bellevue, speaking to the same question, says: "The most important of all agents in arresting and controlling this disease is opium, in some form. Let us see what we gain by its use. The peristaltic movements are retarded or arrested; and thus the inflamed tissues have absolute rest; pain is annulled; emotional excitement is allayed; the nervous system is tranquillized; sleep is secured, and thus the depression of the vital forces resulting from the shock of the attack is lessened."

Professor Clark regarded opium as valuable chiefly in simple, uncomplicated peritonitis. He says: "When the inflammation of the uterus is the dominant lesion and is purulent, opium has little or no control over its fatality, but in the cases in which peritonitis is the ruling lesion, if begun early, it will always shows its power." And yet the clinical features of the six puerperal cases which recovered resembled in all their essential peculiarities the fatal cases reported by Vaché, in many of which the inflammation of the uterus and its appendages was the dominant lesion. Of course, we cannot assert that the cases which recovered had other lesions than those of the peritoneum; but six consecutive cases of peritonitis in the lying-in wards of Bellevue Hospital without any inflammatory changes of the uterus and its appendages, would at the period under review have been regarded as impossible. Especially would this be true in an outbreak, in which the first case rapidly proved fatal with such complications. We would seem, therefore, to be justified in the conclusion that several cases made a satisfactory recovery at that time in which the inflammation of the uterus and appendages was the dominant lesion.

Happily, in these latter days, antisepticism has greatly diminished the frequency of this formidable disease, especially the puerperal form, and in the meantime the remedial measures have been greatly increased. This improvement is due to a more accurate knowledge of the functions of the peritoneum and of the existence and action of pyogenic organisms. The researches of Wegner, Grawitz, and Paulowsky have determined that the peritoneum is quite tolerant of simple wounds and that they heal readily. As a lymph-sac, with stomata in its walls opening into the surrounding lymphatics, the peritoneum is almost directly connected with the spleen, pleura, and other organs, thus admitting of rapid and general infection by peritonitis microbes when they exist in large quantities. The peritoneum is not sensitive to injected fluids, provided they do not contain putrefactive bacteria, and even these organisms may be injected in small quantities without harm, as they are quickly absorbed and destroyed or excreted. But if the peritoneum has been previously irritated or otherwise injured, pathogenic microbes are far more effective. It appears, also, that chemical irritants cause inflammation with hemorrhagic effusion, but without lesion of the intestinal walls or the penetration of microbes into the peritoneal cavity. Peritonitis, therefore, not due to putrefactive organisms, is local, while peritonitis produced by such pathogenic microbes as staphylococcus aureus is rapidly fatal by general infection. One of the most important results of recent researches is the differentiation of the types of peritonitis which are caused by various agencies.

Nearly coincident with our more intimate knowledge of the causes of infectious peritonitis was the discovery of the means by which these pathogenic organisms could be destroyed. As these destructive agents must be applied directly to the microbes, the surgeon was brought into this field of therapeutics and has here won some of his most brilliant victories by boldly opening the peritoneal cavity and cleansing it with germicide solutions. But as there are many types of peritonitis having their causation in various conditions, some being of a microbic and others of a non-microbic origin, it is as yet by no means certain where the line is to be drawn between the medical and surgical treatment of this disease. It is probable that the physician and surgeon will more wisely treat the multiform types of this affection by acting in concert, and discreetly employing the measures which each possesses according as they may jointly interpret the indications.

Whatever may be the possibilities of the art of surgery in the treatment of peritonitis, and they are by no means inconsiderable, the question may be pertinently asked, Has any remedy or combination of remedies, in the hands of the physician, given results equal to, or better than opium, in a series of cases similar to those recorded in this paper? And if it be true that by employing opium, as recommended by Professor Clark,[1] more than fifty per cent. of cases of peritonitis as met with in practice, can be saved, should not this method of treatment be at once adopted in all cases, and the resources of surgery be applied where the manifestations of the disease indicate the necessity of its additional remedial measures?

THE TREATMENT OF HERNIA BY MEANS OF THE HANK TRUSS.[2]

By S. E. MILLIKEN, M.D.,

LECTURER ON HERNIA AT THE NEW YORK POLYCLINIC; ASSISTANT SURGEON HOSPITAL FOR RUPTURED AND CRIPPLED, NEW YORK.

The danger of producing excoriation, or at times severe sloughing, with the ordinary trusses of the shops, makes the treatment of hernia in young and delicate children exceedingly tedious, and occasionally impossible.

It was through the ingenuity of an Englishman, a few years ago, that the hank was converted into a truss. And while nothing new can be said regarding its manufacture, after an experience with it of more than a year, I am led to believe that too little is known of its usefulness. The apparatus (see photos) is composed of a loop or hank of worsted, the best quality, containing twenty-five or thirty strands. This is made sufficiently long that it may encircle the pelvis between the anterior superior and spinous processes and the trochanters major, and have enough to make a perineal strap. On one end a double tape is attached, which corresponds to the affected side of the patient, and should be passed through the loop coming

[1] Professor Clark had a large consulting practice subsequent to this time, and he says, "I have seen many cases in consultation and a decided majority have recovered."

[2] Read before the Surgical Section, New York Academy of Medicine, April 13, 1891.

from the opposite side. Considerable importance should be attached to the adjustment of this loop, and is best described as follows:

With the index finger of the left hand, passed through the loop and allowed to rest perpendicularly on the median line of the abdomen, ordinary tension is made. The tape end is now passed through the loop, and the additional force necessary to bring the point of crossing to the inguinal region will usually give sufficient support to retain the hernia. The free or tape end is carried under the thigh of the affected side, and tied to the band going around the pelvis. Where a double hernia exists, the second band is applied irrespective of the first.

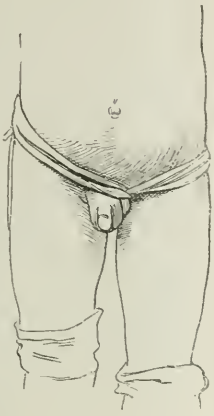

Fig. 1.

The truss may be worn a week or ten days without changing, when the proper use of absorbents is made, the best of which is the subiodide of bismuth. The powder being renewed daily after a sponge bath, rarely will any excoriation of the skin take place.

During the first few weeks no change of the apparatus should be attempted by the mother or nurse, as only after considerable technique has been acquired can protrusion be prevented, especially when dealing with a restless child.

While the ultimate results from treatment have been difficult to obtain, as a large proportion were hospital cases, with the assistance of Mr. Sidney Yankauer, my student, there are before you, I believe, cases that afford sufficient proof of the efficiency and resulting cure without the use of any other appliance.

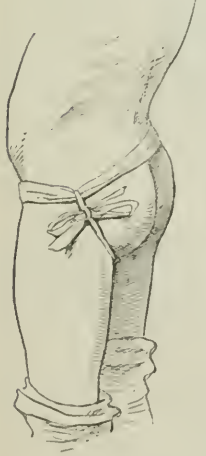

Fig. 2.

Since January, 1890, there have been treated by means of the hank truss, at the Hospital for Ruptured and Crippled, the New York Polyclinic, and in private practice, 268 cases of hernia, ranging from two weeks to four years of age. Of this number there were: Right oblique inguinal hernia, 162; left oblique inguinal hernia, 71; double oblique inguinal hernia, 34; right femoral inguinal hernia, 1. Two hundred and forty cases were males. Twenty-eight were females. The one femoral hernia was in a boy of seventeen months.

While the truss is applicable to hernia in children who are walking, it has proven more satisfactory before that age. Reducible hydrocele and undescended testis can also be relieved by means of this worsted band. When the truss is changed once a week for two months, without allowing the protrusion to take place, ordinarily it can be left off.

The rapid growth of the child, of course, shortens the time of cure, and should the physical condition be impaired, it would be unwise to discontinue the pressure so soon.

Only one case of recurrence has come to my notice after cure with the hank truss. This was only on one side, where a double hernia had formerly existed.

Conclusions.—Among the advantages the hank has over other forms of apparatus are: 1. Easiness of manufacture, no delay being encountered in beginning treatment. 2. Absence of spring or severe elastic pressure, therefore not so liable to excoriation or sloughing. 3. The pressure can be regulated without removing the truss. 4. Less weakening of the tendonous and muscular structures that so frequently follows the use of ordinary trusses. 5. No danger of adenitis from pressure on the inguinal glands.

FRACTURE OF BASE OF SKULL, CAUSING TOTAL PARALYSIS OF BOTH SIXTH CRANIAL NERVES AND PARTIAL PARALYSIS OF THE SENSORY ROOT OF BOTH FIFTH CRANIAL NERVES.

TENOTOMY—ADVANCEMENT OF TENON'S CAPSULE.

By F. B. EATON, M.D.,

OPHTHALMIC AND AURAL SURGEON TO THE GOOD SAMARITAN, AND ST. VINCENT'S HOSPITALS, PORTLAND, ORE.; PROFESSOR OF OPHTHALMOLOGY AND OTOLOGY, MEDICAL DEPARTMENT, UNIVERSITY OF OREGON.

In his invaluable work, "Diseases of the Nervous System," Gowers states[1]: "The nerves that arise nearest the middle line, and are therefore most readily affected by a single lesion, are the third nerves. . . . The two sixth nerves suffer, on the other hand, with great frequency, because they have a long course, not far apart, over the most prominent part of the pons, and they are readily affected by distant pressure. The nerves that are farthest apart, and are least frequently damaged together by a basal lesion, are the two fifth nerves."

As regards the etiology of damage to the fifth pair, he mentions (p. 633), among the causes, traumatic injury, as follows: "Traumatic injury, especially punctured and bullet wounds through the mouth and nose. *On the other hand, the nerve is rarely damaged in fracture of the skull.*" (Italics are mine.) The above statements of this celebrated author would seem to justify me in presenting the following case, which came under my care not long ago:

M. S——, male, aged twenty-four, consulted me February 12, 1891. He stated that he was injured on November 25, 1890, by the caving in of a stony bank into which he and another laborer were making an excavation. When the "cave" occurred, a large bowlder struck him on the left side of the head, felling him to the ground, and he and his companion were covered with a mass of earth. The latter was soon rescued, but it required the joint efforts of several men to remove the rock from the head and shoulder of S——. He then showed no signs of life, and was left for some time as dead, but eventually, in about two hours, he became conscious, and examination disclosed an extensive fracture involving the left parietal and the left side of the frontal bone, and extending downward posteriorly behind the left ear. The lower edge of the fracture was slightly depressed. There was hemorrhage from the right ear and also from the nose. There was no inflammatory reaction, and the patient was on his feet and walking about in twenty days from the time of the accident. He stated that "the right ear and the nose ran red matter for five days after the injury." Moreover, at intervals of about two weeks since, he has had slight hemorrhage from the right ear and nose, and at the same time some headache. When he first regained consciousness he found that both eyes were turned far inward, but that the sight of each was as good as ever, and has remained so. There is some discharge from the right ear, but beyond the inconvenience of having to turn his head to see, and slight dizziness on stooping, he has nothing to complain of.

Present Condition.—Patient appears strong, well nourished, and healthy. On questioning him, however, he stated that he had found himself yet unequal to hard work. The corneæ are at the inner canthi, the right

[1] American edition, p. 481.

being turned slightly more inward than the left. Neither can be turned outward at all, though on telling him to follow my finger when moving it outward before each eye, there was seen the peculiar combined zigzag and rotary motion characteristic of total paralysis of the lateral recti. Motion in all other primary directions was unimpaired; the externi were the only muscles affected. Neither was there any distortion of the face, or paralysis of the facial muscles. Anæsthesia of the face was marked, however, and its area found to be sharply defined on mapping it out with a pin-point. This area is fairly well represented in the cut, which was made from a photograph, the area, the boundaries of which had been obtained by the pin, being filled in on the patient's face, with a black crayon before the picture was taken. I may state that the patient was unaware of the existence of any anæsthesia whatever, until I demonstrated it to him. On applying one pole of a faradic battery to the left eye, the conjunctiva proved to be nearly totally anæsthetic. The cut does not accurately represent the anæsthesia of the frontal region, as it extended, especially on the left side, up under the hair, and back to near the vertex, indicating implication of the supra-orbital, internal frontal, and

FIG. 1.

perhaps of the temporo-auricular, branches of each fifth pair. A remarkable feature of the anæsthesia is the isolation of small non-anæsthetic areas represented by the ultimate distribution of the fibres of the infra-trochlear and orbito-malar branches of the fifth. It will be remembered that the lachrymal is an off-shoot of the ophthalmic, and the two others of the superior maxillary division of the trigeminal. That the lachrymal twig did not escape was indicated by entire loss of sensation in the outer half of each upper lid, while the inner halves retained it. The tip, and the lower part of the nose just above it, also retained sensation, indicating that the superficial branch (externus seu lateralis) of the nasal branch of the ophthalmic division, was intact. The only marked difference between the anæsthesia of the two sides of the face was that that of the right side extended farther backward on the cheek than the left, and that the non-anæsthetic areas of the right side of the lower lip, and around the right eye, also extended more to the right (see Fig. 1). Examination of the right ear disclosed a swollen and perforated membrena, and a moderate muco-purulent discharge. There was no otalgia. The left ear appeared to be normal in every way. I may state that the patient's mental condition seemed absolutely normal, and unusually equable, and his manner quiet and self-possessed.

Course and Treatment.—The young man was urgent that I should begin treatment at once, as he had come to the city on borrowed money; and so I made a tentative trial of Professor J. Michel's method of passive motion[1] on the left eye, grasping it (after cocainizing), to the outer side of the cornea with a pair of fixation forceps, and rotating it outward as far as possible. This procedure, however, gave him so much pain, owing to the secondary contraction of the internus, and the chance of any return of any power in the externus was so uncertain that I of course declined to repeat it. Muscular or capsular advancement was clearly indicated. I decided upon capsular advancement, for reasons which I will explain farther on, operating the right eye February 16th. I proceeded after the modification of de Wecker's original operation, as planned by Professor Knapp, and later on described by him.[2]

After freely tenotomizing the internus I divided the conjunctiva in the ordinary way, but excised none of it. Then Tenon's capsule was freely opened above and below the tendon of the external rectus. A suture was then introduced so as to include the outer lip of the conjunctival wound, the capsule above the tendon, and the upper edge of the latter, bringing it out through the episcleral tissue vertically above the cornea; a second suture was similarly introduced and made to include the lower edge of the tendon. Then a third one was made to include the conjunctiva, capsule, and a considerable portion of the tendon horizontally, coming out in the episcleral tissue close to the outer magin of the cornea. On tying the three, the eye was placed exactly in the middle of the palpebral fissure. I did not aim at any excess of effect, because I believed that I could make up for any after-loss of effect by a similar operation on the left eye. There was moderate reaction on the following day; healing was prompt, and the stitches removed on the fifth day. The eye then retained the position it occupied at the end of the operation. The effect upon the other eye seemed to be marked and unmistakable, for though the paralysis of its externus still remained complete, the cornea was turned some millimètres outward, as if some effect had been produced upon the left internal rectus. The patient now experienced considerable relief, being able to see when holding the head straight to the front, and diplopia annoyed him when the left eye was uncovered. At the expiration of the twelfth day following the operation, the position of the eyes remaining unchanged, I decided to operate the left eye, when, in spite of all warning and persuasion, the patient insisted on leaving the hospital and the city. The warning was thought necessary because a few days before he left he had slight hemorrhage from the right ear and the nose, with headache. This sudden departure was as disappointing as unexpected, since certain points as regards the condition of sensation of the mucous membrane of the mouth and tongue, and possible recovery in part of the sensation of the face, were yet to be studied. Very slight convergence of the right eye then remained.

Remarks.—The interesting feature of this case lies naturally in the nearly symmetrical anæsthesia of the face, while the question of moment is, At what part of the base of the skull was the lesion? Again, What lesion is compatible with nearly symmetrical injury to the sensory root of each fifth, its motor root being intact, while the function of the sixth pair is completely destroyed? Finally, Under the circumstances, can the symptoms be accounted for by injury to the sensory nuclei of the fifth and sixth in the medulla? It is to be borne in mind that the total paralysis of the sixth pair still persisted when I

[1] Zehender's Klinische Monatsblatter, Nov., 1887. p. 373; also Arch. Ophthal., vol. xv., p. 492.

[2] See Trans. Siebenter Periodischer Ophthal. Congress, Heidelberg, 1888, pp. 94, 95.

last saw the patient, that is, over three months after the accident.

A study of the anatomy of the base of the brain will, I believe, justify me in my conclusion that the paralysis of the sixth pair, and sensory root of each fifth pair, could be accounted for best by a lesion occurring just about the middle of the dorsum sellæ of the sphenoid, and that this was at about the point where the sixth pair pierces the dura mater, since the third nerve takes its departure from the brain a little anteriorly, and here also the fifth pierces the dura mater. Moreover, hemorrhage from the right ear persisted so long after the accident that fracture of the petrous portion of the right temporal bone must have occurred, and hence it would seem, at least as far as the sixth pair is concerned, that something more than hemorrhagic effusion destroyed its function, and impaired that of the sensory roots of the fifth nerves. That the injury to the latter did not completely suspend their function, is clearly shown by the areas of sensation shown in Fig. 1, and referred to above. As to the symptoms being compatible with injury to the nuclei of the fifth and sixth in the medulla—while the proximity of the nuclei of the sixth to the floor of the fourth ventricle would seem to render their injury, especially from hemorrhage into the

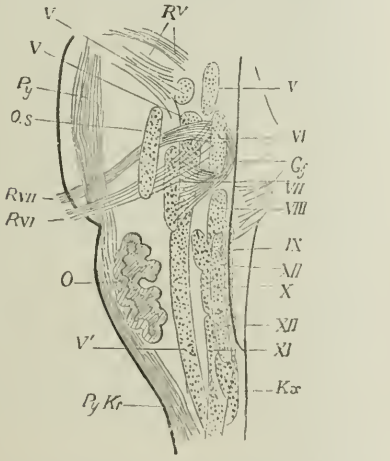

Fig. 2.—Diagrammatic Representation of the Nuclei of the Cranial Nerves as seen in Section. The left half is supposed removed, and the nuclei nearer the median line are shaded darker than the others. (After Erb.)—*Py*, pyramidal tracts; *Py Kr*, decussation of the pyramids; *O*, olivary body; *O.S*, upper olivary body; *V*, motor, *V'*, middle sensory, and *VRV*, lower sensory nucleus of the fifth nerve; *VI*, abducens nucleus; *G.f*, knee of the facial nerve; *VII*, facial nucleus; *VIII*, inner auditory nucleus; *IX*, glosso-pharyngeal nucleus; *X*, vagus nucleus; *XI*, accessorius nucleus; *XII*, hypoglossal nucleus; *Kx*, clavate nucleus; *RV*, roots of fifth nerve; *RVI*, roots of sixth or abducens; *RVII*, roots of facial.—David Ferrier.

ventricle, more likely than to the other adjacent nuclei, such a conclusion seems to me untenable for several reasons.

It is, perhaps, sufficient to cite the principal one, which is: That as pointed by more than one observer,[1] a portion of the fibres of the facial nerve, after leaving its nucleus, pass through the nucleus of the sixth as they circle around it (Fig. 2). I have stated above that the muscles of the face were unaffected; in fact there were no motor symptoms.

In respect to capsular advancement, I would say one word. I have given this operation the preference in all cases of strabismus where a simple tenotomy could not be expected to correct the condition, and have accumulated some experience as to what it will accomplish when properly performed. I can state confidently that the middle horizontal stitch, as advised by Professor Knapp, is, in all cases where a considerable effect must be attained, a most important addition. But to succeed, one must, as he has stated, use a very sharp needle, and penetrate without cutting, the episcleral tissue; otherwise the sutures will accomplish little.

All attempts to discover the whereabouts of my late patient have been unsuccessful.[1]

A CASE OF CONVERGENT SQUINT CORRECTED BY ADAM'S MODIFIED OPERATION FOR DEFLECTED SEPTUM.[2]

By FRANCIS J. QUINLAN, M.D.,

LECTURER ON DISEASES OF NOSE AND THROAT, NEW YORK POLYCLINIC.

The following case came to the Throat and Nose Department of the New York Polyclinic, and was kindly referred to me by Dr. J. W. Gleitsman:

Archie M——, aged fifteen, a boy unusually tall, but thin, for his age, fell from a height about ten years ago and struck on the bridge of his nose. Since that time it was noticed that the boy's eye was turned to the nostril and the nose itself bent in an opposite direction. The patient presented the appearance of one affected with a convergent squint and with extreme deflection of the nose. The voice was high-pitched and decidedly nasal in tone, giving evidence of a continual strain of the vocal muscles. He gave the impression of diminished intelligence, and his countenance pictured the well-marked face of a "mouth-breather."

The boy complained of seeing objects always double, and said he also experienced a feeling as if the affected side of his face were drawn to the nostril.

Little or no attention was paid to the strabismus, which however was of so exaggerated a type, that the cornea of the left eye seemed almost in direct contact with the inner canthus of the orbit, and it was the intention of the writer to send the case to Dr. Webster, for operation on the eye after the boy's nose had been treated.

With the view of remedying the deflection, the interior of the nose was examined, and it was found that the left nostril was completely occluded, so that the smallest probe could not be made to enter the nasal cavity on that side. A twenty per cent. solution of cocaine was thoroughly sprayed over the septal mucous membrane and a small piece of cartilage removed. The boy was then allowed to go home and directed to return to the Clinic in a week or ten days. After a lapse of two weeks the nostril was again examined, and the cavity was found large enough to admit the introduction of the blade of Adam's forceps. In the presence of the class at the Polyclinic.

[1] Wishing to have the opinion of an anatomist as to the point of lesion in this case, I submitted the history to my friend Dr. A. D. Bevan, Professor of Anatomy in Rush Medical College, Chicago. Dr. Bevan kindly responded as follows:

"Portland, Ore., April 7, 1891.

"Dr. F. B. Eaton, City.

"Dear Sir: I have reviewed your report of your very interesting case of paralysis of external recti and anæsthesia of portion of face supplied by fifth nerve, almost symmetrical, as shown by photographs accompanying report. After a somewhat careful study of facts I would give you this opinion as an anatomist as to the character and location of lesion:

"1. As was very clearly shown by the signs following the injury, the patient sustained a fracture of the base of the skull.

"2. The line of fracture probably passed through, or in the immediate neighborhood of, the articulation between the body of the sphenoid and the basilar process of the occipital bones.

"3. Extravasation of blood and thickening of the tissues about the line of fracture produced pressure upon, and paralysis of, the sixth and sensory portion of fifth nerves, both these nerves being in close proximity to the spheno-basilar articulation.

"The fact that the motor portion of the fifth, and part of the sensory portion of the same nerve were not involved would not argue, in my mind, against the causation which I suggest. I would think the prognosis of the case, not permanent paralysis, but eventual restoration of nerve function, if my views of pathological anatomy are correct. Bowlby, in his Injuries of Nerves, reports a somewhat similar lesion (p. 117).

"Thanking you for the opportunity of studying this interesting problem, I am,

"Very respectfully,

"A. D. Bevan."

[2] Read before the Section in Rhinology and Laryngology, New York Academy of Medicine, May 24, 1891.

the septum was fractured and bent to the opposite side. The operation was almost painless and the loss of about a teaspoonful of blood was incurred. Plugs of cotton saturated with Dobell's solution were used to hold the septum in the median position during forty-eight hours, after which time they were replaced by the small nasal tube designed by Dr. Goodwillie.

Our patient (in the meantime) was seen daily, the tube was removed, and the parts cleansed with an alkaline antiseptic wash. Some fragments were removed by the saw and a fairly straight septum resulted, thus admitting to the lungs by a natural passage the air heretofore supplied only by "mouth-breathing;" for it is well known that the combined calibre of the two nostrils is not enough to perform natural respiration in cases of deflected septum, and hence mouth-breathing is called into requisition to make up for this existing deficiency.

The great difficulty heretofore encountered in making Adam's operation a success, was that the means for coaptation, or rather holding the parts in the median line, were rather due to the after-treatment of the operator than to the operation itself. The various plugs of ivory and hard rubber, likewise the clamp, which were designed for the above-named purpose, failed in consequence of the undue pressure which they exerted upon the soft parts, causing œdema, ulceration, and even necrosis of the surrounding tissues.

Perhaps the most interesting and instructive chapter on the etiology of deflections of the nasal septum that has ever appeared, was that published by Dr. Delavan, and read by him before the ninth annual congress of the American Laryngological Association. This beautiful essay is replete with information on the subject, and the author has covered the entire ground by his exhaustive treatise. I should occupy your valuable time were I to go into detail regarding the history of these common disorders, hence I shall simply refer you to Dr. Delavan's brilliant and masterly paper.

Dr. J. W. Gleitsman has more than once entertained us with his practical researches in this special department of medicine, but his valuable paper read before this Section, on "Deflections of the Nasal Septum," has probably been the greatest contribution to the medical literature in this line. Many of you remember this article, and are mindful of the investigation made by Dr. Gleitsman of one hundred skulls found in the various museums and deadhouses of this city. His statistics show the great prevalence of such deflections. The foregoing reference is not made with the view of extolling individuals, but simply to award to those indefatigable workers the credit for their labors and original research on this practically new subject.

You are all familiar with the many operations that have been suggested from time to time for the relief of this condition. Among the most prominent of these are: The Punch of Blandin, the Pin of Robert, the Incision of Asch, and the Fracture of the Parts by the Adam's Forceps. It is this last-named remedy that interests us most, for although the Adam's process by itself would only partly have had the desired effect, the success of the operation was in a measure due to the subsequent use of the soft rubber nasal tube. By this means the resistance of the tissues was overcome and firmly held until all inflammatory action had passed off, and the median position was secured. These tubes prove of invaluable benefit not only in operations of the septum, but also where there is a constant attempt to heal, and a synechia is very frequently the result of a saw operation. They admit air through the nostril, do not interfere with drainage, and keep the tissues erect until firm healing of the parts has taken place. No other method or device can hold the parts so completely without effecting mischief, and no discomfort is experienced through wearing these tubes. Many patients can wear them for six and seven weeks at a time; they can be removed daily, the nose thoroughly sprayed, and the tube washed and replaced. They are so easily manipulated that I have yet to hear of a patient who has so sensitive a mucous membrane as not to be able to tolerate their presence. I can recall distinctly at least fifteen patients who have been operated upon during the past eighteen months and have worn these tubes.

But to return to our present subject. The boy improved daily and realized that a great change had taken place. His family wondered at his altered appearance, for the nose once crooked and deformed had assumed a natural position and the patient experienced great comfort. The hitherto hideously cross eyed boy was observed by friends to have been changed into a pleasant-faced, smiling lad. The interest among his circle was so great that all were glad that he had had his "eyes fixed." Such were the natural feelings of all who knew him, especially of his school companions.

It is a source of regret that a photograph of the boy had not been taken prior to the operation, but so unlooked for a result was not anticipated.

Much has been written from time to time upon the subject of these deflections, and various are the causes assigned to them. Some refer them to the high arch of the palate, others to a hypertrophy of the turbinated tissues, and many cases are directly due to traumatism. We are not here however to dilate upon causes, but to speak of remedying the defects, and to restore the upright position as far as practicable, so that the parts should conform to their natural situation and place. From various observers we are led to believe that the lower two-thirds of the nasal chambers have as their specific function, to receive the air on its way to the lungs, to cleanse it of any foreign particles, and to moisten and warm it before it reaches the pulmonary cavity. If this order is interfered with irritation of the larynx is effected, and congestion of the bronchial mucous membrane as well as an improper oxidation of the blood is the result. Many are the reflex conditions indirectly attributable to the narrowing of the nasal space.

We are all familiar with cases of chorea, rebellious trachoma, and over active lachrymation, purulent otitis, or an aggravated laryngitis, that may have been overcome by attention to the interior of the nose. None can deny that asthma has often been relieved by the removal of a polyp or the reduction of a hypertrophy in this region. If a spasmodic condition of the bronchial muscles can be influenced by lesions of the nostril, it is not difficult to suppose that the muscles of the eye may be affected by similar causes.

The boy in the case before us, up to the time of the injury to the nose, was apparently free from any eye or nose trouble. Immediately after the accident the eye was turned to the nose and the nose itself bent to one side. This condition had existed for ten years, and during that time the boy kept up a continuous muscular tension in order to draw the air through the occluded nostril and exercise his sense of smell. That this strabismus was corrected by an operation of the nose, no one who is cognizant of the facts of the case will deny. No matter how such a result was accomplished, whether the outcome of an operation or a coincidence, it is worthy of comment, and therefore attention to the nasal chambers should be attracted in all eye troubles, to ascertain if some obstructed condition does not exist in these primary channels of respiration.

Some Vaccination Statistics.—In Germany vaccination is compulsory in France it is not. In Germany the total mortality in the entire country from small-pox was 168. In Paris alone during the same year it was 382. In Alsace the annual mortality per 100,000 from small-pox has fallen, since the annexation of the province to Germany, from 2.14 to 0.22. The citizens of Zurich voted to do away with compulsory vaccination in 1883. The number of deaths from small-pox in 1882 was 3; in 1883, 8; in 1885, 52; and in 1886, 85.

Clinical Department.

RUPTURE OF THE RIGHT VENTRICLE — DEATH IN TWENTY-FIVE HOURS — AUTOPSY.

By C. L. SQUIRE, M.D.,

ELMIRA, N. Y.

Was called to see Mr. R. P. W——, March 21, 1891. He was a man seventy-three years of age. His body was well nourished for one of his age. He had regarded himself as well, though he had for a few months been troubled with asthma. Several years ago father had treated him for pleurisy with effusion; his case then required two aspirations, both times the fluid was pure serum.

From this illness he had fully recovered. Since then I have made several examinations of his chest, only to find the lungs in good condition. He had of late been in my office to consult with me in respect to his asthma. I examined his heart and pulse, but could find no sign of organic disease. I passed his case by with the advice to try the inhalation of stramonium smoke. I afterward learned that he had used various of the patent asthma remedies, with little or no relief; I may mention here that within a year he has had some ascites, causing a bulging of the inguinal canal of the right side, and within the same period I have tapped the tunic for hydrocele of the left scrotum. Notwithstanding all this, as I said before, he regarded himself as well, and had even asked his neighbors for odd jobs of work in his line; his occupation was that of a carpenter.

The occasion for my call was a sudden attack of pain in the pit of the stomach, just below the breast bone, which he experienced during an effort at stool. So sudden and distressing was the pain that he had to adjourn the business without further attempt. He adjusted his clothing and walked to the kitchen from the outhouse, then with the aid of his sister and her daughter, he went upstairs to his room and took a seat upon a couch. This occurred at ten o'clock in the morning, and although my visit was one hour and a quarter later, he had obtained no relief, notwithstanding much had been done in the way of hot drinks, hot applications, and foot-baths, by his sister, Mrs. C——. As soon as I entered the room it occurred to me that Mr. W—— was suffering from an ordinary attack of colic, and without making an examination of his case beforehand, began to prepare to give him a hypodermic injection of morphine; fully one-fourth of a grain was used in his right arm. After waiting about twenty minutes and no relief had followed, the same amount was repeated, this time in the wall of the abdomen over the seat of pain; this in twenty minutes more brought some relief, assisted by hot applications of poultices across the chest. Had now been with my patient a full hour, and left him some easier, but I had a conviction that the case was more than simple colic. His pulse was quite natural. His face was a little pale, and some sweat on the forehead was all that indicated the severity of the disease, aside from the moaning and shortness of breath. Returning at three o'clock in the afternoon, found the patient easier than when I had left him three hours before, but the pain was constant and in the same spot. He complained of shortness of breath and a sensation of soreness all through his chest. He had been in bed since he began to be easier. At my request he sat up, so that I could examine his lungs, and strange to say, everything seemed natural, even the heart sounds. The percussion notes were all natural. My fear was pneumonia, but this was now dispelled, and I told Mrs. C—— that some rupture must have taken place, but the exact nature of it I could not tell.

When needed I was to be sent for, thinking this might occur soon. And was a little surprised that no message had been sent during the evening, but was content to let the matter rest until morning. Learned later that the evening and early morning had been passed with no change for the worse, but early in the morning he had attempted to move the bowels again, with renewed pain, which now as before compelled him to desist. He had been quite thirsty during the night and drank milk and water quite freely. He had vomited once, and in the effort he felt a numbness in the left side of the face and absolute blindness in the left eye, but he had recovered from this before my morning visit. When I made my morning visit a great change was found in my patient. He was very restless and in his own words he "could find no place to rest." He was pulseless and gasping for breath. He had all the windows and doors of his room open for air. His ears and finger tips were blue, and a cold whiteness was on his face. He was conscious and talked calmly with his son and with me, constantly changing his position from lying to the sitting posture, with his feet over the side of the bed. He seemed able to help himself. He asked to use the chamber and seated himself upon it, in my presence and with my assistance. As soon as it was learned that he was trying to have a passage from the bowels I remonstrated, and he yielded to my suggestion to go back to bed, and I would remove the mass; but it was found that he could not lie still long enough for me to accomplish much or anything in this respect; still I could discover no great impaction of fæces in the rectum. I had been with him two or three hours, using whiskey to stimulate him, but it was with no good effect. He had been pulseless all this time, neither could I hear or detect a heart-sound with my ear to the chest, but this was attributed to the hurried and labored breathing, the sounds of which muffled the feeble heart-sounds. At this juncture he asked me if I could do nothing for him. I answered that the time was short in which to do anything, but that we would stimulate him the best that we could; then, turning to his son, said that it was my opinion that the case was one of heart rupture, and that medicine could do the patient no good.

The patient then repeated a passage of Scripture: "Yea, though I walk through the valley of the shadow of death I will fear no evil: for Thou art with me," etc. A few other such lines, and he sank into silent death. At first an autopsy was refused me, later consent was obtained under restrictions. Five hours after death, Dr. C. W. M. Brown present: The cartilages were found ossified, so much so, that they were cut through with difficulty, but this accomplished the chest was opened and examined. Very little blood was found in the pericardium. Pressing on the heart, a jet of blood came from within and was wiped away with a sponge; again the heart was pressed upon, and again the jet appeared to come from the right ventricle through an opening about the size of a knitting-needle. The heart was removed and found enlarged; the walls of the right ventricle were cut through and found to be very much softened in texture; the walls of the left ventricle were found hypertrophied; the left auricle collapsed, the right auricle greatly distended. Examining the anterior wall of the right ventricle more closely, another and larger rent was found; it was about a fourth of an inch long, and at right angles to the ventricular ridge, and about one and three-fourths inch from the auricle. A probe could be passed through this into the cavity of the ventricle by displacing a blood clot that had plugged it tightly. The other opening, through which the jet of blood had been observed to come, was one inch higher up and a half inch anterior to the ventricle ridge; this was regarded as more recent in its occurrence than the former. Near the apex there was an indenture that looked to me to be the cicatrix of an old rupture, but Dr. Brown thought not; this was over the right ventricle also. The internal opening of these ruptures was at the top of the cavity and behind the anterior valve. There was no disease of the valves themselves, no disease of the lungs or pleura except a

pigmentation of the lung-tissue, which is often observed in cases of mitral or tri-cuspid lesions. Having verified my diagnosis and established the cause of death, the examination was carried no further.

ABSCESS OF THE PENIS, COMPLICATING PERIURETHRITIS, WITHOUT PERFORATION OF THE URETHRA.

By JAMES M. MAGHEE, M.D.,
WEST ORANGE, N. J.

W. B——, aged eighteen, student, applied to me, April 1st, for treatment of a gonorrhœa contracted about a week previous. His penis was somewhat swollen, and discharging freely from the meatus. Ordered rest and local applications of a lead and opium wash with oleoresin of cubebs ℥. x. t.i.d.

April 4th. Penis very much swollen and very tender, hardly any discharge. On the under surface, midway between the fossa navicularis and the bulb was a hard, painful swelling extending toward the dorsum on the left side. An incision was advised, but refused. Flaxseed poultices applied.

April 6th. The swelling had increased in size, and at a central portion gave a distinct fluctuation. It was so painful as to seriously interfere with sleep. The patient's scruples against the knife were finally overcome, and an incision made to the left of, and parallel with, the course of the urethra and a large quantity of pus evacuated. A probe passed in almost to the dorsum on the left side and disclosed a sinus extending over the urethra to the right. The cavity was well syringed out with a five per cent. solution of carbolic acid and packed with iodoform gauze, and the poultices ordered continued. The next day almost complete relief from pain was experienced, and the swelling had nearly subsided. For his gonorrhœa I ordered, in addition to the cubebs, an injection of zinc sulphate (gr. ij. ℥ i.) four times a day. The abscess was well washed out daily with the carbolic solution, and packed loosely with gauze soaked in balsam of Peru. Poultices discontinued.

April 10th. There had been considerable sloughing around the incision, and from the bottom of the cavity large unhealthy granulations had sprung up. The discharge was very profuse and rather fetid. No urine escaped from the wound. The granulations were touched with nitrate of silver, and the cavity washed out with a solution of mercuric chloride (1 to 3,000).

April 12th. There seemed to be an increase in the size of the abscess cavity. It now involved the principal portion of the corpus spongiosum on the left side for the space of about an inch in the centre of the penis, and quite a pocket had formed extending to the right. A counter-opening was made at the bottom of this pocket, and a strip of gauze run through as drainage. The whole cavity was then swabbed out with chloride of zinc (gr. xl.- ℥ j.) and packed as before.

April 15th. Condition about the same. Potassii iodidi was ordered in doses of gr. v., t.i.d., increasing gr. ij. ss. per day. Dressing as before. In a few days the improvement was marked, and continued.

May 8th. The main cavity had completely healed, and only a small sinus connected the two openings, with very little discharge. The patient was now taking gr. xx. of the iodide, t.i.d. He was ordered to decrease gr. ij. ss. per day, and to stop in two weeks. At this time he returned to college, and I did not see him again until June 18th, when he reported cured. The wounds in the penis had completely healed, he said, about May 15th, and his gonorrhœa had ceased running nearly two weeks previous. At no time during the course of the trouble had there been the slightest discharge of urine from the wound, although he was made to evacuate his bladder at each dressing, and the condition noted carefully. The latter part of August a 30 (French) sound, which was the largest the meatus would admit, was passed into the bladder without difficulty. The penis is somewhat curved during erection, and a small cicatrix remains to mark the site of the original incision, but he complains of no inconvenience and says the curvature is growing less and less all the time.

As nearly all cases of extensive abscess complicating periurethritis are followed by acquired hypospadias more or less severe and permanent, it is interesting to note in this case that, in spite of the large portion of the tissue around the urethra involved in the suppurating process, and the sloughing which occurred, the urethra itself remained intact, and that three months later no narrowing of the canal could be detected.

STRANGULATED CÆCAL HERNIA, EXTRA-PERITONEAL—HERNIOTOMY, NECESSITATING ABDOMINAL SECTION, COMPLICATED BY MITRAL AND AORTIC INSUFFICIENCY —RECOVERY.

By J. EDWARD AUSTIN, M.D.,
NEW YORK.

Cases of this form of hernia are extremely rare. Treves,[1] in a short monograph on the subject read before the Medical Society of London, says: "Hernia of the cæcum occurs most commonly in congenital umbilical herniæ. In inguinal herniæ it is less frequently met with, and but seldom found in femoral. The acquired hernia is commonest in the inguinal region in adult males, and on the right side. Clinically the hernia is irreducible as the effect of its bulk, adhesions, and peritoneal connections, and also from its liability to inflame and become obstructed, but rarely strangulated. Modern text-books generally state that it has no sac. Arnaud's case was the first on record, being one for which he performed resection in 1732. The patient recovered—a permanent fæcal fistula being left." Mr. Treves maintains that all cases of cæcal herniæ possess a sac, and in the majority of cases it is perfect. He gives a careful description of the history of the statement that hernia was sacless, commencing with Desault, who affirmed the point in 1796, passing on to Scarpa[2] who asserted that the peritoneum had the same arrangement in the sac as in the abdomen, in which belief he was succeeded by Pelletau, Hesselbach, Cloquet, Laurence,[3] and Chelius. There are seven specimens in the museums of London, and eight recent records of cases. Of these fifteen cases twelve were provided with perfect sacs, two had imperfect sacs, and one was doubtful. Treves himself reports two cases in both of which the sac was perfect. In one hundred examinations of fresh subjects in the post-mortem room, Treves found the cæcum entirely invested with peritoneum, and no meso-cæcum.

Wright[4] reports seven cases of cæcal hernia in male children from three months to seven years of age, the hernia occurring in the right inguinal region, and a perfect and well-defined sac in every case. Bennett[5] reports a case of cæcal hernia entirely wanting in a peritoneal sac, in which strangulation at the internal abdominal ring co-existed with an intussusception through the ileo-cæcal valve. Mr. Bennett states that in 565 herniotomies performed at St. George's Hospital the number of cases of strangulated hernia of the cæcum in any form amounted to only 1.59 per cent. Hulke[6] mentions two cases of strangulated cæcal hernia, one inguinal and one femoral, operated upon at the Middlesex Hospital. In the former case the cæcum and appendix were extra peritoneal, while the ascending colon was surrounded by a complete sac. Keetley[7] reports a case of hernia of the appendix vermiformis in the right inguinal region, with

absence of peritoneal sac. Schmidt,[1] Gray,[2] Black,[3] report cases of strangulated cæcal hernia in the left inguinal region.

I have not been able to find in the literature of the subject to which I have had access another case of recent strangulated cæcal hernia. All of the reported cases have occurred secondarily in pre-existing old standing scrotal hernia. The following case occurred in my practice while Chief Surgeon to the railroad at Limon, Costa Rica. The duration of the strangulation—sixty-five hours—the fact of it being a recent hernia, the previous history and physical condition of the patient, make the case one of great interest.

J. W——, aged twenty five, Jamaica negro, a laborer on the railroad, entered the Limon Hospital, March 13, 1890. He had been previously admitted to the hospital on January 18, 1890, suffering from acute tropical dysentery. At this time he was extremely weak and anæmic, with dyspnœa on exertion and œdema of the feet and ankles. He stated that three years before he had had a severe attack of rheumatism in Jamaica. Physical examination revealed enlargement of the heart (dilatation), with both mitral systolic and aortic diastolic murmurs. He made a good recovery from the attack of dysentery, but was kept in the hospital until February 26th, on account of his cardiac trouble. He requested his discharge upon that date as he felt able to return to work. His general condition was much improved, and the œdema and dyspnœa had disappeared under appropriate medication.

On admission, March 13th, 9 A.M., he gave the following history: He had been employed in a mason's gang, sixty miles from Limon, and on March 10th, about four P.M., while lifting a heavy stone, he "felt something give way inside of his belly," and a large swelling appeared in the right side of his scrotum. It caused him intense pain, and all his efforts to push it back were ineffectual. With help he managed to walk back to camp—a short distance away—and went to bed. Unfortunately, just at this time—owing to the heavy rains—several landslides occurred, completely blocking the road, and not until the morning of March 13th was communication established and the patient brought into Limon. In the interim he was advised by some of the negroes in camp to take castor-oil, which he did, also four pil. cathartic co., U. S. Vomiting soon commenced, and continued, at intervals, with severe abdominal pain of a colicky nature. (The limited intelligence of the patient made it impossible to obtain a satisfactory account of the character of the vomited material.) The day following the rupture, although suffering great pain and vomiting frequently, he took two more doses of castor-oil and four more cathartic pills.

On admission the patient appeared to be suffering intensely; was unable to stand. Face anxious; tongue dry and brown. Severe abdominal pain; no movement of the bowels since the rupture; vomiting up to the hour of admission. Examination revealed a large scrotal tumor on the right side, the size of an infant's head. Tumor very tense and extremely sensitive to touch. No impulse on coughing. Abdominal tenderness on the right side. Temperature, 101° F.; pulse, 116; respiration, 28. Patient was immediately anæsthetized and herniotomy performed under antiseptic precautions. Carefully cutting down on the tumor, a quantity of loose areolar tissue was seen at the bottom of the wound. Separating this with the handle of the scalpel, the vermiform appendix came into view. Further exploration revealed that the hernia consisted of the whole of the cæcum and about three inches of the ascending colon. There was no trace of any peritoneal sac. The cæcum was partially adherent to the scrotal tissues, but the appendix was free. The cæcum and involved portion of the colon were deeply congested, being dark purplish red in color. The cæcum presented two small ecchymotic spots and flakes of exuded lymph upon its surface. The constriction was found to be at the internal ring, and was freely divided. Half an hour was spent in carefully separating the adhesions of the cæcum. When this was completed it was found impossible to reduce the hernia through the natural openings, on account of its bulk and the inflamed condition of the parts. The abdominal wall, including the parietal peritoneum, was then divided upward, and a little outward, for four inches, with scissors, the finger being used as a director.

At this stage of the operation it was clearly apparent that there was an entire absence of peritoneal sac, the peritoneum having been stripped off on the descent of the hernia. The parts were then returned to the abdominal cavity, which was flushed out with hot sublimate solution, 1 to 10,000. Wound closed by deep and superficial sutures, drainage-tube introduced, and dressed antiseptically.

Patient bore the operation badly, symptoms of severe shock supervening soon after its commencement. Rallied under brandy and camphor in ether given hypodermically.

March 14th.—Passed a fair night; was given morphia, ¼ gr., every three hours. He complained of considerable pain in the abdomen on the right side. Temperature, 101.8° F.; pulse 120. Kept under morphia and given stimulants and beef juice at stated intervals.

March 16th.—Bowels moved twice spontaneously; some abdominal pain; temperature normal.

March 20th.—Deep abdominal sutures removed; wound healed by first intention. Localized tenderness over the cæcum on pressure.

April 4th.—Allowed solid food and to be up about the ward.

April 16th.—Patient left the hospital and returned to his home in Jamaica. The cicatrix was firm; some induration existed on the right iliac fossa, but no tenderness on pressure.

172 West Ninety-fifth Street.

A CASE OF SPURIOUS MEMBRANA TYMPANI.

By CHARLES H. BAKER, M.D.,
BAY CITY, MICH.

Mrs. E——, aged thirty, consulted me, November 25, 1890, regarding her deafness, which dated back three or four years. She had suffered with otorrhœa for several years, at intervals, and on the complete cessation of the discharge, which occurred spontaneously, her hearing was greatly impaired. She consulted an aurist two years ago, and, according to her account, he perforated the false membrane, at that time in the ear, with improvement in the hearing, but the opening closed in one night.

No further efforts to improve the hearing were made for two years, until she came under my care. Examination showed the drum of the left ear absent, and hearing gone. In the right ear, about one fourth inch external to the normal position of the drum, and parallel to it, was a grayish, parchment like membrane resembling a thickened membrana tympani, which crackled, on being touched with a probe, loud enough to be heard by persons standing near; it completely occluded the auditory canal. The patient could understand very loud conversation only when looking at the speaker, and heard a watch only on contact.

I made a crucial incision in the membrane, from the cut edges of which bloody serum slowly exuded, showing it to be living tissue, although the incision was not painful. The flaps thus formed were cut off, the edges of the ring forming the border were cauterized with chromic acid, and a firm cotton pledget inserted in the opening. The tympanic cavity was empty, the membrane and ossicles being entirely absent, and the Eustachian tube was pervious. By the perforation the hearing was imme-

diately improved to the hearing of ordinary conversation in the same room, and a soft-ticking watch at six inches.

The following day there was considerable discharge of pus from the ear, and the portion of the canal between the spurious drum and tympanic wall rapidly filled with a tough plug of pus and epithelium, which adhered firmly to the surface and was separated with difficulty. The discharge of pus and accumulation of this toughened material was arrested, in a few days, by insufflations of salicylate of chinoline and boracic acid, and in ten days the patient was discharged with the opening nearly the full size of the canal and no appearance of irritation anywhere in the ear. Two or three weeks afterward the patient's husband told me that her hearing "was as good as anybody's."

On January 3d she returned, with the hearing nearly as bad as ever and the membrane reformed. It was again incised and cut away and kept open with cotton plugs. In two days it reformed again, the tampon having been left out. I then made an eyelet of a piece of hard-rubber tubing, five thirty-seconds of an inch in diameter, one-eighth inch bore, and one-eighth inch long, grooved in the edge. This was placed in the opening, and in one night the membrane closed into the groove, binding the eyelet fast, and it has remained in place ever since, the patient having good hearing and no discharge from the ear.

Doctor A. H. Buck reports, in his "Manual of Diseases of the Ear," p. 96, an exactly similar case, the description of which fits this one in most particulars, but at the last time the patient was seen there was a muco-purulent discharge still present which may have prevented the membrane reforming. C. H. Burnett reports analogous cases, except that the membranes did not entirely occlude the canal, and quotes Buck's case. Gruber ("Diseases of the Ear," 1890) does not mention such a case, and I do not find any others reported. In all the reported cases there were granulations springing from the walls of the canal, which coalesced, and by their union and cicatrization formed the membrane; but in my case there were no such granulations, and the only formative agent appeared to be the epithelium extruded from the canal wall.

When the membrane was reforming it had the appearance presented by skin-grafts growing on an ulcer, and I think the growth was a true hypertrophy of the epithelium covering the ring, which formed the border of the membrane, this ring being inflammatory in its origin.

Progress of Medical Science.

What Constitutes a Filth Disease? This question is answered by Dr. S. W. Abbott in the *Sanitarian*, as follows: We may reasonably conclude that a filth disease is one in relation to which filth in some form or other, either wet or dry, plays the part of an important factor only in its causation, but is not itself the direct cause; that it acts either as a favorable soil for the propagation of disease germs (other favorable conditions also existing), or that it acts as a suitable medium or vehicle for the transmission of the particulate contagion from the sick to the well, as is probably the case in the inhalation of the bacillus tuberculosis in and with the dust of filthy or ill-ventilated apartments. We may also conclude that the filth which promotes the spread of infectious diseases is specific filth, and hence the necessity of removing all filth is that thereby we are sure to remove the specific filth, or that which contains the germs of infectious disease. The point which the author desires to emphasize is, not that the removal of filth should in the least degree be discouraged, but that, when done, it should be done intelligently and with this principle in view: that filth is a condition rather than a cause; that it is the soil for the culture and transmission of infection, and not the infection itself; and just so far as the principle of infection is deprived of its proper soil, so far is one of the most important conditions of its growth and propagation removed. In the field of sanitation, the careful watching for and providing against the introduction of infectious disease, the isolation of the sick, the disinfection of houses, clothing, and other associated material, are as essential as the removal of that other condition to which attention has especially been directed.

Tumors and Tissue Insubordination.—At a recent meeting of the Royal Medical and Chirurgical Society, Professor Humphry raised an interesting question as to the etiology and nature of congenital overgrowths as compared with neoplasms of later advent. He regards these growths, whatever the particular form they may assume, as instances of tissue insubordination, thus developing a thesis embodied in the College of Surgeons' lectures on cancer, of a year or two since, by Mr. John Marshall, who suggested that malignant growths were due to the uncontrolled activity of cells which had escaped from the grasp of the nervous system. We are, it must be admitted, profoundly ignorant of the laws regulating symmetry of growth. We can only suggest, in one of those grandiloquent, but not very expressive, phrases so dear to the metaphysicist, that "forms and shapes are determined by the balance of pressure of contending forces." The idea of tissue insubordination is a plausible one, but who shall determine whether the force at work is insubordination or an influence more powerful than subordination? No essential difference can be, or at any rate has been, made out between the embryonic, or congenital, and post-embryonic growths Why a child should be born with a finger rivalling the leg in point of size, is as difficult to understand and explain as why, without obvious cause, a sarcomatous or other neoplasm should arise in later life. The assertion that the force which presides over organized forms is the same as that which confers certain definite shapes on crystals, only takes us from one dark room into another. The discussion of these abstruse points of philosophical physiology is doubtless an excellent training for the reasoning faculties, but, fortunately, therapeutics does not stand still while the rival claims of the "included germs" and other theories are being adjudicated upon.

Hepatic Cirrhosis in Children.—Cirrhosis of the liver is rare in children, if those cases be excepted which are due to congenital syphilis. This form of cirrhosis may be seen at birth, for it is even then of some standing. Dr. Blanche Edwards chiefly concerns herself with the part played by the infective maladies in bringing about cirrhosis of the liver. In a table of cases of this disease collected by her, as many as thirteen out of one hundred were of tubercular origin, and in eight of these tubercular peritonitis was the cause. Hepatic cirrhosis with ascites may be taken for tubercular peritonitis. It is hardly necessary to point to the congestion of the liver which takes place in the eruptive fevers. It is demonstrated by the bilious form sometimes shown by these febrile diseases. The finding of definite and lasting change in the liver after these acute diseases, just as such changes have been found in the kidney after scarlet fever, diphtheria, etc., is only one step further, and this has been proved by Laure and Honorat, who found lesions in the liver in five cases of measles. Thus, while the infective maladies may produce, as far as the liver is concerned, a chronic cirrhosis, it has been acknowledged that an interstitial nephritis may be due to them. P. Marie has pointed out, in addition, the part played by these illnesses in producing diseases of the nervous system—disseminated sclerosis, for instance. Cardiac disease was the most frequent cause of cirrhosis of the liver, and out of the one hundred cases, alcohol accounted for eleven. As to the morbid anatomy, sometimes the liver is enlarged, sometimes it is diminished in size, at one time red and soft, at another yellow and indurated. Here the process is generalized, and there it is

limited to a lobe, or present only in small islets. The interlobular vessels are dilated and their walls thickened. There is a proliferation of the connective tissue which sometimes penetrates into the lobule—the cells at the periphery being disorganized. The small bile-ducts are also increased in numbers. Hudels recognizes in syphilitic cirrhosis three stages: 1, Vascular engorgement; 2, infiltration with embryonic elements; 3, infiltration organized into connective tissue, viz., interstitial syphilitic hepatitis. This infiltration may be localized either as the miliary syphiloma or the gummatous nodule. In the first stage the liver is large, soft, reddish-brown or reddish-violet; later, when sclerosis has taken place, it is small and hard. If this evolution is distinctly known, as it is in syphilis, it is impossible not to recognize it in other infective maladies, when in some cases it has been proved that there is engorgement of the liver with proliferation of leucocytes when the patient dies early in the course of measles, and that there is sclerosis of the liver if the patient die late in the disease. Alongside the cirrhotic changes in cases of the syphilitic liver, there may be lardaceous degeneration—the amylo-gummatous form. Gastric symptoms, which are ordinarily so common in children, may hardly arrest the attention. There may be hemorrhages from the stomach, from the nose, sometimes into the skin, or a chronic urticaria. But two symptoms, jaundice and ascites, are especially frequent. The authoress says that instead of being opposed as they are in the adult, they are often present together. Their intensity varies, but in the cirrhosis following alcoholic poisoning or scarlet fever, ascites is prominent. Œdema of the legs occasionally occurs. Dilatation of the veins over the abdomen is very frequent. Renal cirrhosis occurred in one-fifth of the cases. Rises of temperature are often seen. The patient usually dies of cachexia, sometimes of hemorrhages.—*Le Progrès Médical.*

Condurango and Condurangin.—The following are the conclusions formulated by Dr. Guyenot as a result of a series of experiments made to test the therapeutic value of these substances: 1. Condurango employed in the form of a powder appears to be remarkably efficacious in painful affections of the stomach, and especially in the case of gastric ulcer and irritation of the gastric mucous membrane. 2. Cases of cancer of the stomach, which have been claimed to be cured as the result of treatment with condurango, are certainly to be regarded as errors in diagnosis. In all probability the majority of them were cases of ulcerative gastritis. 3. Condurangin possesses an extremely curious and interesting action. It causes a veritable locomotor ataxia, which is due, without doubt, in view of its late appearance, to the formation of some toxic substance produced by the splitting up of condurangin in the organism. 4. In view of the fact that the chemical nature of condurangin is not yet thoroughly established, and its physiological action not being thoroughly understood, the bark of condurango should be employed in therapeutics, and not condurangin.—*Therapeutic Gazette.*

Treatment of Organic Strictures of the Urethra.—The following are the conclusions of an article on this subject published by Dr. J. William White, in the *University Medical Magazine* for March, 1891: 1. Strictures of large calibre, that is, of more than 15 French, situated at or behind the bulbo-membranous urethra, are to be treated, almost without exception, by gradual dilatation. 2. Strictures of large calibre occupying the pendulous urethra are to be treated by gradual dilatation when very recent and soft, and by internal urethrotomy when of longer standing, distinctly fibrous in character, or non-dilatable. It is to be remembered that the great majority of so-called strictures of large calibre of the pendulous urethra are merely points of physiological narrowing. 3. Strictures of the meatus and of the neighborhood of the fossa navicularis should be divided upon the floor of the urethra whenever it is evident that they are real pathological conditions producing definite symptoms, and not normal points of narrowing. 4. Strictures of small calibre (less than 15 French), situated in advance of the bulbo-membranous junction, unless seen very early and found to be unusually soft and dilatable, furnish the typical condition for internal urethrotomy, which should be done preferably with a dilating urethrotome and, invariably, with all possible antiseptic precautions. 5. Strictures of small calibres (less than 15 French), situated at, or deeper than, the bulbo-membranous junction, should be treated whenever possible by gradual dilatation. In a case of resilient, irritable, or traumatic stricture in this region, or of stricture which, for any reason (as the occurrence of rigors), is non-dilatable, external perineal urethrotomy is the operation of choice. 6. Strictures of the deep urethra, permeable only to filiform bougies, should be treated by gradual dilatation when possible, the filiform being left *in situ* for some time, and followed by the introduction of others, or used as a guide for a tunnelled catheter. If the stricture be not suitable for dilatation, external perineal urethrotomy should be performed. 7. Impassable strictures of the deep urethra always require the performance of perineal section.

Treatment of Boils.—Dr. Veiel, at the annual meeting of German physicians held at Bremen, stated that he had used in the treatment of furunculosis a paste consisting of equal parts of oxide of zinc and vaseline, to which was added four per cent. boric acid. This ointment was thickly spread on lint. In cases of circumscribed furunculosis the paste was rubbed in and around the diseased parts three times daily. If the affection was universal, the whole body was rubbed with the application. Sublimate baths were at the same time used when the patient could bear them. In a case of universal furunculosis a perfect cure was obtained in seven weeks. Large boils were poulticed.—*Lancet-Clinic.*

The Treatment of Sprains.—Dr. Duhamel recommends warmly the use of a plaster composed of one part of carbonate of lead in two parts of olive-oil as an application to sprained joints. He heard of this remedy when on a visit in Holland, and on his return to France immediately put it to trial in a number of cases. Most of the cases were sprains of the ankle, and the patients were made to walk as soon as the plaster and retaining dressings had been applied. All these cases made a rapid recovery, but one case of a sprain of the wrist, in which the same remedy was applied, did not improve. The cure was obtained in all probability by the exercise of the joint rather than by any especial virtue residing in the white lead.

Morphine by Insufflation.—Dr. Von Klein claims that better effects are obtained by insufflation of morphine into the nostrils than by hypodermic injection of the same quantity. The action of the drug is observed more speedily and its effects continue longer.

Thyroid Transplantation for Myxœdema.—At a meeting of the Hospitals Medical Society of Paris, held November 14, 1890, M. Merklan presented a woman, forty-one years of age, almost a dwarf, who had, since the age of ten, suffered from well-marked myxœdema. For some years it had been noticed that the occurrence of attacks of uterine, nasal, and gingival hemorrhages coincided with an aggravation of the classical symptoms, which, conversely, receded on the cessation of the losses. The treatment adopted (seventy-two days previous to the date of the report), viz., the transplantation of one lobe of the thyroid of a living sheep to the cellular tissue of the right submammary region of the patient, determined the permanent cessation of the hemorrhages (within three days), a diminution of the infiltration of the face, and, to a marked extent, of the supraclavicular and mammary regions, a great improvement in locomotive power, and in the general health of the patient.

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, May 30, 1891.

THE MORTALITY FROM CHLOROFORM NARCOSIS.

THE question of the relative safety of ether and chloroform is pretty well settled in the minds of most surgeons. Yet as long as it is settled in an exactly opposite way by Americans and Europeans, the matter will continue to be discussed with interest.

The prevailing belief is that statistics will show about one death in 25,000 anæsthetizations for ether, and one in 2,500 for chloroform.

Dr. Weir, however, from a careful study of the New York Hospital statistics, found that the ratio of deaths from ether was six in 12,000 operations, or one to 2,000, a very much higher rate.

Some statistics of great interest have just been collected by Professor Gurlt and reported before the German Surgical Congress. The figures were obtained from sixty-six hospitals, mostly in Germany, and including the Berlin Charité.

Deducting (for some reason) the Charité figures, 24,675 cases of anæsthetization were reported. Of the whole number 22,656 were with chloroform, 470 with ether, 1,055 with ether *plus* chloroform, 470 with ether *plus* chloroform *plus* alcohol, and 27 with bromide of ethyl. Among the chloroform cases 71 cases of threatened asphyxia and 6 deaths occurred; among the ether cases, none even of danger; among the ether-chloroform cases, 5 of danger; among the ether-chloroform-alcohol cases, 4 of danger; among the bromide of ethyl cases, none. The chloroform used was obtained mostly from German and English chloral factories. Of 2,732 narcoses, 278 lasted an hour or more. The three longest lasted 150, 155, and 180 minutes. The average consumption of chloroform with the ordinary mask was one gramme per minute; with the Junker-Kappler mask 0.6 of a gramme. One private clinic reckoned the average consumption at twenty-five grammes per case; the maximum consumption was 180 grammes. Some of the reporters increased the narcosis by injecting morphia. The threatening of asphyxia occurred in patients of all ages and degrees of strength.

The six deaths among 22,656 cases of chloroform narcosis make the ratio about one to 3,700. This is lower than that obtained for ether from the records of the New York Hospital.

A recent article by Professor Kocher (*Correspondenz-blatt f. Schweitzer Aertzte*) sums up very well the views of an experienced surgeon, and shows that in some European clinics, at least, ether is gaining ground. Kocher says: 1, As a rule, no attempt to produce general anæsthesia should be made without close examination and thorough preparation of the patient; 2, it is advisable, and in many cases necessary, before administering an anæsthetic, to arouse the action of the heart by giving alcohol or some other stimulant; 3, the patient should always be laid in the horizontal position; 4, chloroform should never be given in cases in which the patient has not been sufficiently prepared; in tooth extraction, reduction or dislocation, and, indeed, most minor surgical operations, ether should always be substituted for chloroform; 5, in cases of cardiac disease and of disturbance of the heart's action not associated with respiratory disturbances, ether should be given and not chloroform; 6, in patients suffering from diseases of the respiratory organs, associated with hyperæmia of the tracheal and bronchial mucous membrane, ether should be rejected and chloroform administered in its place; 7, in cases of prolonged surgical operation chloroform should be carefully administered at first, the state of anæsthesia being subsequently maintained by the continuous inhalation of small quantities of ether; 8, the inspired air should never be allowed to become saturated with the vapor of chloroform; 9, when, in any case in which the operation is likely to be a long one, the administration of ether is contra-indicated and chloroform must consequently be used, a previous injection of morphine should be practised in order that anæsthesia may be produced by a smaller quantity of this agent.

SMALL INTESTINAL DIGESTION.

SOME often hitherto accepted views regarding intestinal digestion will have to be changed, if the observations recently published [1] by Drs. MacFadyen, Wencki, and Sieber are correct.

These observations were made upon a female patient in whom an intestinal fistula had been produced at a point just above the ileo-cæcal valve. The fistula was the result of an operation for hernia with grangrene. The intestine below the fistulous opening was closed, and for six months all the chyme passed out through the artificial anus. During this time the patient was well nourished, gained in weight and eliminated a normal amount of urea. The flow of the chyme from the fistula was continuous though less at night. It was found that it takes about two hours for food to pass from the mouth to the cæcum, though it requires nine to fourteen hours for the whole meal to reach that point.

Curiously enough it was noticed that the chyme was more fluid and diarrhœal on an albuminous than on a vegetable diet.

As regards the nature and properties of the evacuated materials, says *The Lancet*, it is noticeable that they were almost free from odor, containing hardly any products of albuminous disintegration, such as indol and sulphuretted hydrogen; they were slightly acid in reaction, tinged yellow by bilirubin, and, according to the predominance of flesh or starchy matter in the food, showed muscle fibre,

[1] Archiv. f. Exp. Path. u. Pharmacol. Bd. xxviii. (Hft. 3, 4.)—Lancet.

albuminous granules, vegetable fibres, starch granules, etc., and invariably a large number of various forms of bacteria. The filtrate yielded albumin, mucin, peptone, dextrose, the two forms of lactic acid, acetic acid, and the biliary acids and bilirubin.

The number and varieties of bacteria were very great, some being special to the intestine, others being common to it and the mouth. These bacteria appear to be chiefly concerned in causing disintegration of the carbohydrates into lactic, acetic, succinic and other acids. We are also told that the intestines produce a small amount of ethylic alcohol, so that every man has a little still of his own, and total abstinence is a physiological impossibility.

There has always been contradictory evidence regarding the reaction of the intestinal contents, but it has generally been believed that the acid products of the stomach digestion were made alkaline by the bile, pancreatic, and intestinal secretions. These are not sufficient, however, according to the present investigators, on account of the organic acids developed by breaking up of carbohydrates. The reaction of the contents of the small intestine is therefore feebly acid. This applies, however, only to its lower part. It is probable that in the jejunum the reaction is alkaline. If, however, the intestinal contents get too acid mucin is precipitated and there is a mucous diarrhœa.

VETERINARY MEDICINE AND THE UNITED STATES GOVERNMENT.

The Bureau of Animal Industry of the Department of Agriculture has done excellent scientific work, and is under the charge of competent men, but it is difficult to see why it should go into the business of publishing veterinary medical works. A volume entitled "Special Report on Diseases of the Horse," has, however, recently been issued by it, printed at the Government's expense. The contents have been prepared by several well-known veterinarians, and we have no doubt that the book is a good one. There is no reason, however, why the farmer and horse owner should have a volume prepared for his special help, while other citizens have to buy their books at regular rates. The practice, if logically extended, would end in furnishing to the public, manuals on the diseases of the dog, of birds, and finally on man himself. The United States Government as publisher of a volume "Every Man his Own Doctor," would furnish a fine spectacle of paternalism.

THE BRAIN OF LAURA BRIDGMAN.

Everyone has read accounts of Laura Bridgman and of the marvellous results obtained by Dr. Howe in educating her. Losing her sight, hearing, and nearly all sense of smell and taste at the age of two, she remained practically without education until the age of nearly eight years, when she was placed under Dr. Howe's care. A careful record of her intellectual progress was kept for many years, and in 1878 Professor Stanley Hall made a valuable series of physiological and psychological tests upon her. She was shown to have some sense of taste, but practically none of smell. She could not hear even the loudest noise, but appreciated vibrations. Rotation mader her dizzy. Her tactile sense was two or three times more acute than normal. Mentally she was eccentric, but not defective; she lacked certain data of thought, but not the ability to use what data she possessed. Her emotions were very lively and she had a certain hysterical tendency. She died in 1889, at the age of sixty. Her brain was obtained, and has been studied by Dr. H. H. Donaldson, of Clark University (*American Journal of Psychology*, September, 1890).

Dr. Donaldson's report is a model of careful scientific work, and contains much of interest to students of anatomy. But his findings are decidedly meagre and show little more than would be expected. The brain weighed about one thousand two hundred grammes. This is considerably below the average for women, which for Anglo-Saxon and German races is about one thousand two hundred and seventy-five. Considering her small stature and body-weight, the brain, however, was not especially small.

An examination of the lobes and convolutions showed that there was some defect in the centres for articulate language; also defect in the occipital lobes, especially the right (visual centre), and in the temporal lobes, especially the tips. This last condition may have been due to her imperfect sense of smell and taste. The fissure of Sylvius was short, and the posterior corpora quadrigemina small. A careful microscopical examination might give some important information as to the central course of the optic and olfactory tracts, but this has not yet been done. There was nothing in the appearance of the brain which would ally it to low-type, criminal, and insane brains.

THE PREVENTION OF PHTHISIS.

The high rate of mortality from phthisis induced the State Board of Health of New Hampshire to secure the opinion of the physicians of that State upon certain points in connection with the disease, such as its cause, frequency, preventability, treatment, etc. To this end blanks were sent to all physicians of the State asking them to answer nineteen stated questions. The returns were exceedingly complete, and as reported in the recently issued annual report of the State Board of Health, make interesting reading. A summary is almost impossible but the Board presents the following:

The chief causes and the preventative measures to be employed in the disease may be summarized, in the light of our present knowledge of the disease, as follows:

1. Pulmonary phthisis is the most fatal disease known to civilization.

2. The *bacillus tuberculosis* is generally believed to be the cause of the disease.

3. The disease, when developed after the first years of childhood, is acquired and not inherited, although there may be an inherited predisposition which renders the subject incapable of resisting the invasion of the bacilli.

4. The disease is liable to appear at any period of life.

5. That there is great danger arising from the use of tuberculous meat and milk. From the evidence which has been gathered we are led to believe the liability to infection from these sources is very great and to insure

public protection in this particular the State should exercise a careful supervision of our milk and meat supplies.

6. That the greatest danger of infection is from the sputa of the consumptive. For this reason, when confined to the house, a spit-cup or spittoon should be used, and when upon the street a handkerchief to receive the expectorations. The spit cup or spittoon might preferably contain a disinfectant, but if these vessels are frequently and thoroughly cleansed with boiling water, disinfectants are not an absolute necessity. The handkerchiefs should be immersed in boiling water at least once daily before the sputum has become dried.

7. No person should occupy a sleeping room with another who has tuberculosis, although many persons escape infection under such conditions.

8. The eating utensils of a consumptive should be washed in boiling water, and care should be exercised that the same glasses, spoons. etc., are not, before being washed, used by children and others. The patient should avoid kissing others or placing in his mouth any article likely to be used or handled by others.

9. The dejections of consumptive patients in cases where the bowels are affected should be thoroughly disinfected.

10. Perfect cleanliness of the apartments occupied by consumptives should be urged in all cases. The bed-linen, towels, etc., should be very frequently put through the operations of the laundry, while the walls should be frequently cleansed and dressed anew. In fact the whole question of restriction may be expressed in the one word "cleanliness."

A PLEA FOR PUBLIC BATHS.

The City of New York expends over three and a half millions annually in charitable work, and furnishes relief of various kinds to over half a million of people. Most of this work is for the care of the sick and helpless, and it, no doubt, is of the highest value in relieving the poor and unfortunate. Dr. S. Baruch, however, who gives the above figures in an article entitled "A Plea for Public Baths" (*Dietetic Gazette*, May, 1891), calls attention to the fact that while so much is done to help sickness and distress, comparatively little is done, aside from the watch over infectious fevers, to prevent it. And among the most important of preventive measures he rightly places personal cleanliness. In an interesting review of the history of public baths, we are told that at one time Rome possessed 856 of these institutions, and used 400,000,000 gallons of water in supplying them. The price of admission averaged about one-third of a cent, so that they were practically free. In later times the use of public baths was very common, and it seems that it is only in these later days that they have fallen into some neglect. A change, however, in this respect is taking place. In London, Brussels, Vienna, Berlin, and many of the smaller cities of Germany, these institutions have been provided by the local government or benevolent societies.

New York has not entirely neglected the matter. The city has erected fifteen public swimming-baths which are open four months in the year, and in which last year the total attendance was 2,700,000. That sufficiently proves the popularity of such institutions, and shows with equal emphasis the need of their extension. The use of the floating-baths, however, could not be extended into the cold months without enormous expense; hence Dr. Baruch's suggestion that there be constructed numerous places where rain- or shower-baths can be had. Baths of this kind can be supplied at a minimum of expense and maximum of utility as regards both cleanliness and enjoyment. Nor are they in any sense an experiment. In Berlin, where public rain-baths have been established, the attendance in six months was 103,000, at an individual expense of two and a half to twelve and a half cents. They have been equally successful in Vienna, Magdeburg, Cologne, and several other cities of Germany. Already the Society for Improving the Condition of the Poor, of New York, has begun the construction of a People's Bath-house, which is intended to accommodate 500 daily.

The good work is begun, but it is evident that a single establishment must prove very inadequate, however great its individual capacity. There should be a number of baths distributed throughout the city and convenient to the tenement-house population. We see no reason why the city should not undertake this work since it would redound so much to the health of the people.

Said Dr. Hufeland: "I regard cleanliness and the cultivation of the skin as the chief means for the prolongation of life."

The American people in the past have acquired a rather unenviable reputation for their niggardliness in supplying themselves with bathing facilities. It is a reproach which ought to be removed, and the establishment of public baths in our great cities will do much to promote this end.

THE DAY OF THE PATHOLOGIST.

Dr. J. Mitchell Banks, of Liverpool, thinks it is at hand. In his inaugural address, "Some Observations on Medical Education," he says, in reference to the best use of time and energy in learning how to be a doctor, and in reference to sciences destined to prove of utmost value in after-life to the medical aspirant: "To affirm that botany is of any practical utility to a doctor in his profession is absurd. When men made their own tinctures and infusions from the plants which they gathered with their own hands, botany might have been of some use. . . . With regard to zoölogy, I am told that the student who has dissected his frogs and worms and limpets is in a much better position to commence the study of human anatomy than one who has not. For the sake of argument I will admit that he is so at the commencement of the winter session. Long before the end thereof his advantage is gone. In a very few weeks the perfectly fresh student picks up his anatomical terms, and sees his way about his dissection, while the gentleman who has spent a good deal of time in the company of the frog finds that his knowledge does not help him much with the relations of the femoral artery or the prostate gland. And the same criticism applies to chemistry, where the amount of knowledge forced into the student is infinitely beyond what the exigencies of his profession will ever require from him. . . . Take the enormous field of pathology and morbid anatomy. You wish the student to understand the use of the microscope. What better field for its use? You wish to perfect his manual

dexterity. I know of nothing more useful to this end than the dissecting and mounting of morbid specimens. . . . And if you want to teach your student habits of methodical study, is not the classification of disease as good for that purpose as the classification of plants? Does he want to learn how to observe carefully and record accurately? Is not the making of one autopsy as valuable in that respect as the dissection of many limpets? Our neglect of pathology and morbid anatomy in this country has been simply shameful. The Germans have beaten us out of the field in this respect. We are slowly waking up to our defects in this matter, and the day of the pathologist is coming. I hail it with joy, and I do not care if his science drives out of the field all the so-called preliminary studies I have been tilting at. Their bearing upon true medicine is almost *nil*. As a means of mental training they offer nothing which the study of pathology cannot give too. While the student is working at that he feels that he is acquiring knowledge which will serve him in good stead every day of his life—knowledge, moreover, which he can only learn during his student career, because, when he enters into practice, the post-mortem room and the laboratory are no longer within his reach."

TREATMENT OF EXTRA-UTERINE PREGNANCY.

The *Gazette des Hôpitaux*, February 3, 1891, finds in A. W. Gilchrist's "Thèse de Paris" upon the subject of ectopic gestation many practical suggestions of which the following are perhaps the most important: The discovery or mere suspicion of extra-uterine pregnancy before the fifth month is an indication for laparotomy. In event of intra-peritoneal rupture, laparotomy becomes at once an urgent necessity. If, however, the rupture is simply intra-ligamentary, sagging, or tearing, surgical interference is not imperative unless signs of hemorrhage suggest imminent rupture of the sac and effusion into the peritoneum. After the fifth month, and before the ninth, interference of any kind is only justifiable under the following conditions: 1, When there is death of the fœtus and some complication resulting from it; 2, in event of secondary rupture of the sac; 3, when signs of intolerance of the pregnant state are present. Ectopic gestation on term calls for the usual operation, modified according to modern progress in laparotomy. This is the only procedure then to be recommended. Signs of the death of the fœtus at or near term necessitate an immediate laparotomy. An old suppurating fœtal cyst should be treated as a case of pelvic abscess. Elythrotomy is for exceptional cases only, and so are perincotomy, the parasacral incision, and pelvic extraction. Puncture, injection, and electricity, always dangerous and unreliable, should be rejected as unsuitable measures. Care of the secundines varies according to circumstances. In the simple interstitial form enucleation is the best method. In case the placenta is diffuse and adherent to the abdominal viscera, everything should be closed up with the greatest care and left in its original position. Evidences of septicæmia or intolerance of the presence of the secundines calls for a secondary laparotomy. If the placenta is dense, in which case it is but slightly adherent, it may be removed. Total extirpation of the placenta, whenever practicable, is always the best way to dispose of it.

TREATMENT IN FRIEDREICH'S DISEASE.

In *Brain* (Part LII.) appears Dr. P. Ladame's exhaustive treatise on hereditary ataxia, in which occurs the following, in substance, concerning treatment: As prophylactic measures in the case of predisposed children, sound hygiene, hydrotherapy, rational gymnastics, careful education, and intelligent supervision to prevent fatal habits of masturbation that would hasten the downward progress of the disorder by exhausting an already feeble spinal cord, are of first importance. In the antecedents of those suffering from this disease, excesses in Onanism and alcoholism are frequent items of family history. Applications of continuous currents, ten to fourteen milliampères three times a week, stabile and labile, to the vertebral column by means of large electrodes, give a sensation of well-being to the patient that lasts for some time. He is apparently stronger, more active, and less uncertain. This treatment alone, continued for years at regular intervals, may possibly arrest the progress of Friedreich's disease. The second method is that of suspension, recommended by M. Charcot, by which some good results have been obtained at the Salpêtrière. Three hundred suspensions resulted in improvement in speech and in the general condition in one of Dr. Ladame's cases. The ataxia and weakness of the extremities have not been at all modified; the club-foot, scoliosis, nystagmus, abolition of knee-jerk, and choreiform instability still remain. Would more have been gained by employing Sayre's jacket, as was suggested by Gilles de la Tourette? The author thinks not; adding, however, that it is a medical duty to try everything in a disease against which there is as yet no efficacious means of treatment.

News of the Week.

Female Druggists.—The Russian universities are to establish courses for the instruction of young women as druggists.

The Influenza has been prevailing to an alarming degree in Norway. The mortality in Christiana has increased ten per cent.

Sexual Perversions.—In a paper on this subject, by Dr. Kiernan (*Alienist and Neurologist*), the author stated that a New York male physician with a large practice always wore feminine dress.

A Chance for Female Doctors.—The State Civil Service Commission will hold an examination for lady physicians to State insane asylums in the Capitol at Albany, on June 11th. All who reside in the State and have had one year's experience in hospital practice or three years' general medical practice are free to compete.

Dr. Koch, according to a German paper, has the bad habit of sitting up late at night and not rising until nine o'clock. We are also told that he takes soup for breakfast instead of coffee, and drinks much soda-water with his dinner.

Ether Drinking in Michigan.—A correspondent communicates to *The Medical Age* the prevalence of one sort of ether drinking—the compound spirits of ether—in the northern counties of the State of Michigan, principally among the Finns, Swedes, and Poles. It is generally consumed with alcohol or whiskey.

Cases in Obstetrics.—An interesting tabulation of the first 1,000 cases of obstetrics in the Sloan Maternity Hospital, New York City, appears in the pages of the last issue of the *American Journal of Obstetrics*. The oldest patient confined was forty-six years of age, while the youngest was twelve years and ten months of age. The largest number (659) were between twenty and thirty years of age. Also in the largest number (547) it was the first pregnancy, while in one case occurring in the table it was the patient's seventeenth confinement. Of the presentations 936 were vertex, and of these 610 occupied the L. O. A. position. As to operative interference, there were 112 in which it was required, as follows: induction of labor, 12; forceps, 83; version, 14; craniotomy, 3. Of twin cases there were 13, about 1 in 77 of the whole number of women delivered. In the forceps cases the returns are certainly noteworthy. Out of the 83 cases none of the mothers died. Of the 84 children 75 were living, 9 still born, including premature twins. In nearly all the cases the long curved forceps (McLane's) were used, both in high and low operations. Of the fatal cases in this report we have as causes, chronic Bright's disease, 1; rupture of uterus, 1; placenta prævia, 1; placenta prævia with contracted pelvis, 1; eclampsia, 1; septicæmia, 1; total, 6. On analyzing these deaths it is seen that one was from chronic organic disease and not labor; in another the patient was moribund when taken from the ambulance; in a third—placenta prævia—there was much delay and great bleeding before assistance could be given. The septicæmia case was admitted while in the second stage of labor, and was in a very filthy condition. The showing, therefore, is highly creditable.—*Journal of American Medical Association.*

An Anxious Doctor.—The following clipping from the Elk Hart (Indiana) *Review* has been sent to *The Medical News:* One of our physicians recently received the following letter from a country physician (?): "Dear dock I hav a pashunt whos phisicol sines shoes that the windpipe has ulcerated of, and his lung have drop intoo his stumick. he is unabel to swoller and I feer his stumick tube is gon. I hav giv hym evry thing without efeckt. his father is welthy, Onerable and influenshial. he is an active membber off the M. E. Chirsch and god nose I dont want too loose hym. what shal I due. ans. buy returne male. yours in neede."

A Fund to Establish a Four Years' Medical Course in the University of Pennsylvania.—The Board of Trustees of the University of Pennsylvania, at their meeting last Thursday, received from Dr. William Pepper, Provost of the Medical Faculty, an offer of $50,000 toward a permanent endowment fund of $250,000 for the medical department, and $1,000 annually toward a guarantee fund of $20,000 a year for five years. This offer is made subject to the provisions that the University shall decide, before June 1st, that it will establish a four-year obligatory graded course of medical study, to be established before September 1, 1893; also, that the endowment and guarantee funds be fully subscribed before January 1, 1893. Dr. Pepper's letter was accompanied by a communication from the Medical Faculty pledging it to carry out the proposal for the four years' course. The members of the Faculty have subscribed $10,000 a year for five years toward the guarantee fund, which is to cover any present deficit in the operation of the new plan.

The Academy of Medicine of Baltimore is defunct. Instituted in May, 1877, by a number of the older physicians of the city, it began an unpopular career by requiring that candidates for membership should have been ten years in practice. Later it relaxed so far as to permit those excluded, to enter upon the presentation of an acceptable thesis.

A New Private Polyclinical Institute of some importance, and on a large scale, has just been opened in Berlin. It is to go by the name of the "Johanneum." The institute is to combine hospital practice with clinical instruction and theoretical research. It contains eighty beds, is furnished with laboratories, microscope rooms, etc., an electro-mechanical institute, and a lecture theatre, in which courses are to be given by Professor Eulenburg on diseases of the nervous system; by Professor Zülzer on diseases of the kidneys and bladder; and by Dr. Scheimann on diseases of the nose and throat.

A Counterblast to Alcohol.—Professor Forel has recently published an address delivered by him to the students of Christiania and Upsala on "Drinking Habits: their Hygienic and Social Importance, and their Relations to Academic Youth" (Enke, Stuttgart). His thesis may be stated in his own words as follows: "Alcohol, together with the worship of the Golden Calf, is the true Devil of the nineteenth century." Professor Forel vehemently denies all virtue to alcohol, whether as a stimulant or a food; he refuses to admit that it is a source of national wealth, a question on which finance ministers are apt to hold a different opinion. As showing the enormous quantity of alcoholic drink taken even by persons who might be supposed to be ethically as well as educationally superior to the common herd, Dr. Forel gives the following extraordinary statistics as to the amount of intoxicating liquor consumed at a public banquet during the International Medical Congress at Berlin last August. The number of guests was 4,000, and among them these thirsty souls—representing, be it remembered, the very head and front of the medical profession throughout the civilized world—drank 15,382 bottles of wine, 22 hectolitres of Bavarian beer, and 300 glasses of brandy. "Can we wonder," says the *British Medical Journal*, "that scenes the reverse of edifying are said to have followed this Gargantuan symposium?" From other sources we are much inclined to question the correctness of Forel's figures.

American Association of Andrology and Syphilology.—The fifth meeting of this Association will take place in Washington, D. C., on September 22–25, 1891, in connection with the Congress of American Physicians and Surgeons. Daily sessions will be held from 9 A.M. to 1 P.M. *Preliminary Programme.*—The following papers have been promised: "A Review of the Evidence of the

Transmission of Syphilis to the Third Generation," by Dr. Abner Post, of Boston; "Relation of Syphilis to Stricture of the Rectum," by Dr. R. W. Taylor, of New York; "Surgery of the Ureter," by Dr. A. T. Cabot, of Boston; "Some Experience with Suprapubic and Perineal Drainage, Temporary and Permanent, in Vesical Disease," by Dr. Edward L. Keyes, of New York; "Some Cases Illustrating Urinary Retention from Unusual Causes," by Dr. Francis S. Watson, of Boston; "On the Radical Cure of Urethral Stricture by Restoration of the Mucous Membrane to the Normal Condition," by Dr. John P. B. Bryson, of St. Louis; "Observations upon the Syphilitic Cachexia," by Dr. J. Blake White, of New York; "An Obscure Case of Chronic Non-specific Urethritis of Sixteen Years' Standing," by Dr. George E. Brewer, of New York; "New Methods for the Treatment of Urethral Disease Effected by the Use of the Speculum," by Dr. F. Tilden Brown, of New York; "Rupture of the Bladder," by Dr. A. T. Cabot, of Boston; "Encysted Stone, Complicated with Growths of the Bladder," By Dr. C. H. Mastin, of Mobile; "Short Note on a Case of Urinary Tuberculosis Treated by the (Koch) Subcutaneous Method," by Dr. Edward L. Keyes, of New York; "On the Use of Salicylic Acid in the Treatment of Certain Forms of Cystitis," by Dr. John P. Bryson, of St. Louis; "The Dry Poultice in the Treatment of Epididymitis," by Dr. George E. Brewer, of New York; "Exhibition of an Antiseptic Syringe for Hypodermic Medication," by Dr. J. Blake White, of New York; "On the Occurrence of Nephritis in Early Syphilis," by Dr. J. A. Fordyce, of New York. J. A. Fordyce, *Secretary*.

How to Get a Sugarless Milk.—Milk is usually forbidden diabetics on account of the sugar (galactose and dextrose) which it contains. Dr. A. E. Wright has discovered a method of making sugarless milk (*British Medical Journal*). Take a quantity of milk, dilute it with three or four volumes of water, to which 1 to 2 parts per 1,000 of acetic acid have been added. This produces a precipitation of all the casein and fat of the milk. The precipitate is allowed to settle for a few minutes, and then strained through a piece of calico. The precipitate is then washed, and redissolved in a one per cent. solution of the following mixture of salts:

	PARTS
Sodium chloride	11.5
Potassium chloride	9.9
Monopotassium phosphate	13.8
Dipotassium phosphate	10.0
Citrate of potassium	5.9
Dimagnesium phosphate	4.0
Magnesium citrate	4.4
Dicalcium phosphate	8.0
Tricalcium phosphate	9.6
Calcium citrate	25.5
Calcium oxide	5.5
Sodium carbonate	40.0

A trace of saccharin may be used to sweeten the milk, and the salt solution is best used at about blood temperature, and the casein and fat precipitate is to be mixed up with it, as in making cocoa, to the desired thickness. We obtain by this easy method a very fairly palatable and entirely sugarless milk. The precipitated casein and fat can also be dried without undergoing alteration, and then used for the preparation of the milk.

Bequests to Medical Charities.—By the will of the late Mr. John T. Farish, who died in this city on May 13th, charitable bequests are made to St. Luke's Hospital, $50,000; Home for Incurables, $50,000; New York Cancer Hospital, $25,000; Hospital for Ruptured and Crippled, Nursery and Child's Hospital, House of Rest for Consumptives, and Manhattan Eye and Ear Hospital, each $10,000.

Artificial Quinine.—"This is the discovery of the week; indeed, we may say of the year," says the Paris correspondent of the *Lancet*. "The synthesis of that useful, nay, indispensable substance, quinine, has long been a desideratum, and now, thanks to MM. Grimaux and Arnaud (the former Professor of Chemistry at the École Polytechnique, and the latter having succeeded the late illustrious centenarian, Chevreul, at the Muséum d'Histoire Naturelle) the chemical dream has been realized. The method adopted by these gentlemen is as follows: The base cuprein contained in the shrub Remijia pedunculata, growing in Brazil, is treated with sodium, then the combination thus obtained is chloride of methyl. The product is quinine absolutely identical with the substance with which we are familiar."

University of the State of New York, Examination Department.—The following amendment to chapter 507 laws of New York, 1890, was approved by the Governor on May 4, taking effect immediately, as chapter 311 of the laws of 1891:

"This act shall not apply to any student who duly matriculated in some legally incorporated medical college of the State of New York before the 5th day of June, 1889, provided that such student shall file with the secretary of the board of regents of the University of the State of New York, a certificate setting forth the fact of such matriculation, verified by the applicant and signed by the secretary of the faculty of the college at which he matriculated."

This act will exempt only such students as file the required certificate in the Regents' office, on or before August 4, 1891. The following is the form of the certificate:

It is hereby certified that was on 18 duly registered on its official records as a fully matriculated medical student in

Signed, —— — ,
Secretary of the Faculty.

State of New York
City of } *ss.*
County of

being duly sworn says that he is the identical person referred to in the above certificate and that all the statements therein set forth are true.

Sworn to before me
this day of 1891.

—— — ,
Notary Public.

Accepting Albany Medical College Library by the State.—The Governor has signed the bill providing for the acceptance by the State of the Albany Medical College Library, and appropriating $5,000 for taking proper care of the same.

The St. Francis Hospital, New York.—Dr. Edmund C. Wendt has resigned his position as curator of the St. Francis Hospital.

The Seventh International Congress of Hygiene and Demography will be held in London, August 10–17, 1891. The meetings of the Section of Preventive Medicine will be held under the presidency of Sir Joseph Fayrer in Burlington House, Piccadilly, on Tuesday, Wednesday, Thursday, and Friday, August 11th, 12th, 13th, and 14th, between 10 A.M. and 4 P.M. On Tuesday, August 11th, after a short address by the President, a discussion will be held upon "The Mode of Preventing the Spread of Epidemic Disease from one Country to Another." The discussion will be opened by Surgeon-General J. M. Cunningham, C.S.I., of London. On Wednesday, August 12th, a discussion will be held upon "Diphtheria, with Special Reference to its Distribution and to the Need for Comprehensive and Systematic Enquiry into the Causes of its Prevalence in Certain Countries or Parts of Countries, with a View to its Prevention." The discussion will be opened by Dr. Edward Seaton, of London, and continued by leading representatives of France and America. On Thursday, August 13th, a discussion will be held upon "The Relation of Alcoholism to Public Health, and the Methods to be Adopted for its Prevention." The discussion will be opened by Sir Dyce Duckworth, LL.D., M.D., of London, and by Professor Westergaard, of Copenhagen. On Friday, August 14th, papers on miscellaneous subjects will be read and discussed. A list of papers accepted by the Section will be published later. Gentlemen who are desirous of joining the Congress and taking part in any of the above discussions, or of communicating papers on other subjects within the scope of the Section, are requested to inform the Honorary Secretaries of the Section not later than June 15th. Abstracts of papers to be read in the Section must be furnished to the Honorary Secretaries not later than June 15th; and the full text of the papers before July 15th. Communications respecting the Section should be addressed to

DR. ISAMBARD OWEN,
40 Curzon Street,
London, W.

How to Remove Superfluous Hairs.—"Doctor" asks: Can you or some of the readers of your journal give me a reliable preparation for removing superfluous hairs without using electricity?

The Midwifery Dispensary.—We have received the first annual report of this institution for the year 1890. During the year, 330 applications were made, of which number, 199 women were attended in labor, the others being referred to other institutions or seeking other attendence. The objects of the dispensary are to provide lying-in women with competent medical attendance in their own homes, and at the same time to obtain the material for practical obstetrical teaching to medical students. This institution does not appear liable to the objection which we have so often urged against dispensaries in general, since the patients are obtained from a class that seldom seeks medical aid in childbirth, being usually content with the services of an ignorant midwife or of some charitably disposed neighbor. The procuring for students of practical clinical instruction under the supervision of competent instructors supplies a want that has hitherto been very imperfectly met. The advantage of obstetrical practice in the homes of the patients rather than in well appointed hospitals, is another feature of the work that commends itself at once. The dispensary is located at 312 Broome Street.

The Association of American Medical Colleges.—The following officers were elected at the annual meeting of this association in Washington, in May, 1891: *President*, N. S. Dows, of Chicago: *First Vice-President*, L. McLane Tiffany, of Baltimore; *Second Vice-President*, P. O. Hooper, of Little Rock; *Secretary* and *Treasurer*, Perry H. Millard, of St. Paul.

The German Congress of Internal Medicine met at Wiesbaden, April 8th to 12th, under the presidency of Professor Leyden.

Dr. Naunym read a paper on "Diseases due to Gall-stones." He said that in the aged there are often but few symptoms, so that during life no diagnosis is made; for whereas among younger persons five to six per cent., or even ten to twelve per cent., of all bodies examined contain gall-stones, in aged subjects the proportion is much higher. According to Schröder, women are affected five times as frequently as men; before thirty they are rare; about twenty-five per cent. of the cases occur after sixty. Women who have borne children suffer more than others. It is inferred, therefore, that conditions causing stagnation of bile are the cause of the affection, such as pregnancies, tight-lacing, etc. The type of costal respiration in females is a favoring circumstance. The frequency of the affection in the aged points also to stagnation due to atony. Artificial inspissation of bile does not form calculi, nor does the precipitation of insoluble substances; but it is is far more probable that they arise exclusively from a change in the epithelium of the mucous membrane of the bile-ducts. The phenomena of the disease may be divided into regular typical cholelithiasis and irregular atypical forms, the latter often leading to cancer, and therefore of bad prognosis. As to treatment, he remarked that but little was to be expected from so-called solvents, as it had been shown that only very small amounts—of poison, for example—passed into the bile. The effect of "cholagogue" remedies so generally prescribed had been left in doubt by experiment. A mixed diet causes a larger flow of bile than any drug, and solvent remedies are irrational, since the bile itself is a complete solvent for material contained in it. The excretion of bile must be mechanically aided by improved clothing. The use of salicylic acid, etc., to prevent bacterial infection is not of much service. Since every error in diet brings on attacks, a main indication is strict dieting. The good effect of Carlsbad waters is perhaps due to excitation of peristalsis. Surgical treatment has, owing to the position of the gall-bladder, a fair prospect of good results, and in many cases the gall-bladder should be entirely removed. It is usual in practice to regard jaundice as the chief symptom, but very often there is no jaundice present, and the suffering in such cases is often only regarded as gastralgia.

Iodism may be prevented, it is said, by the administration of five grains of bicarbonate of sodium three times a day.

Society Reports.

American Medical Association.

FORTY-SECOND ANNUAL MEETING.

Held in Washington, D. C., Tuesday, Wednesday, Thursday, and Friday, May 5, 6, 7, *and* 8, 1891.

(Continued from page 609.)

OBSTETRIC SECTION

SECOND DAY, WEDNESDAY, MAY 6TH.

The Treatment of Accidental Abortion was the subject of a paper by DR. BEDFORD BROWN, of Alexandria, Va. The paper was the result of the observation and care of more than two hundred cases of accidental abortion occurring during an experience of forty years. When called to a case he gives first $\frac{1}{4}$ grain morphia, and $\frac{1}{60}$ grain sulphate of atropia hypodermically. And if there is much hemorrhage and depression, $\frac{1}{60}$ grain strychnia and 20 minims of ergot to induce contraction of the arterial system and strengthen the heart. Then douche the vagina thoroughly with hot water containing permanganate of potash. If the hemorrhage still continues, a pint of hot water containing an ounce or more of alum is thrown into the vagina. This cleanses it of all coagula and causes decided contraction of the os uteri, and the formation of a fine clot in the cervical canal, which, acting as a plug, arrests hemorrhage for a time and does not increase the tendency to abortion as does the tampon. These measures failing and matters becoming serious, he packs the vagina with iodoform gauze. This failing, he passes the dilator into the cervix and injects three drachms of ergot into the rectum. This induces forcible uterine contractions and forces the fœtus and secundines through the dilated os. In the event that the placenta is still retained, we then have one of the most embarrassing complications of abortion. He has little faith in ergot for the arrest of hemorrhage in retained placenta or for the expulsion of that body. In the delivery of retained placenta, he has long since discarded all instruments as hooks, forceps, and curettes as unsatisfactory, and relies on the fingers alone. At the fourth month and after he has found it necessary to introduce the entire hand into the uterus, so as to be able to remove the retained placenta. In abortion the placenta and its retentions are the cause of more anxiety, trouble and annoyance than all other questions. The resultant hemorrhage, the sepsis, the local inflammations, the organic changes, the subinvolutions and septicæmia arising from its retentions, render its early, prompt, and thorough removal a matter of paramount importance. Safety, speed, and completeness are the principal questions for consideration. The use of the tampon to restrain hemorrhage in retained placenta is not wise, if we can avoid it. The principle is unwise and unscientific. It seals up a putrefying, sepsis-generating mass of animal matter in an organ, which we would not dare do in any other organ of the body. He was fond of the iodoform gauze conicals-haped tampon, introduced on the screw dilator into the cervix in cases at the third month, dilating the os one and a quarter inch, then douching the vagina with a hot antiseptic solution, and three drachms of the fluid extract of ergot thrown into the rectum. To counteract collapse he uses successfully morphia, atropia, and strychnia hypodermatically, also sometimes whiskey, while he favors the injection of hot water 110° F. with a little chloride of sodium and bicarbonate of soda. This is given by a hypodermic syringe holding an ounce, and twelve or fifteen of them are given, thus adding about a pint of warm fluid to the circulation. An enema of hot beef-tea and water is also an advantage. Absolute rest of mind and body in the recumbent position is very necessary.

Can the Gynecologist Aid the Alienist in Institutions for the Insane? was the subject discussed with great vigor by DR. I. S. STONE, of Washington. The doctor had systematically investigated the present status of medical practice in the institutions for the insane in many of the States. His investigations opened up the fact that the superintendents of asylums, with but few creditable exceptions, felt themselves competent to treat all phases of diseases of woman, or in fact to be full fledged specialists in all departments, and were not at all gracious to outsiders, especially gynecologists, who might endeavor to offer aid. To his inquiry, "Can the gynecologist aid the alienist in institutions for the insane?" he received largely negative replies. He drew the inference that asylum superintendents thought gynecologists meddlesome and bungling men who did more harm than good. So far as he was able to determine, female diseases were seldom recognized, much less treated, by these superintendents, and he propounded the query, "Why is it that insane women apparently do not have the same diseases that afflict so many sane members of their sex?" The doctor urged in closing that the fullest details be obtained, that we may know the real relation between diseases of the female pelvic organs and insanity.

DR. BYRON STANTON, of Cincinnati, said that when a man became an asylum superintendent he ceased to be a competent doctor.

DR. JOSEPH EASTMAN, of Indianapolis, reported a case where a woman was incarcerated in an asylum for a year and discharged hopelessly insane, and then cured by an operation at his hands. This, too, when the possibility of female trouble had been suggested before she entered the asylum, and frequently during her stay there. The superintendent would have it that it was nothing but a neurosis, and that she was incurable. The extent of her cure may be known by the fact that she now occupies the position that she held before her insanity, viz., lady superintendent of schools. The operation performed in this case was the removal of the appendages, and was necessitated by the finding on exploratory incision that one of the Fallopian tubes was bent sharply on itself and bound down tightly by a peritonitic adhesion. In operation on patients insane from self-abuse he had been completely successful in one case, and partially so in another.

DR. J. H. MCINTYRE, of St. Louis, added his testimony to that of Dr. Stone.

DR. EDWIN WALKER, of Indianapolis, thought a very large number of our cases were neuroses, though some of them were doubtless due to gynecological troubles.

DR. C. A. L. REED, of Cincinnati, who has written a *brochure* on this subject, called Dr. W. W. Potter, of Buffalo, to the chair, and said that he had given this subject serious attention for a number of years. He was satisfied of the sound scientific basis for reform which would involve the appointment, not only of gynecologists but of specialists in all other departments, as staff officers to asylums. The fact unearthed by Dr. Stone, that the alienists did not want the assistance of anyone else in the care of the insane, revealed an alarming state of affairs. The claim that the medical superintendent, who is generally a housekeeper, a gardener, a jailor, and who at the same time was competent to treat diseases of the eye and the ear, of the lungs, pelvis, and every other special organ, was preposterous. The claim is made, however, by these gentlemen, and is a clear demonstration of their pretentiousness. The doctor challenged any superintendent of this class to an experiment, the result of which would be as interesting to science as startling to humanity. He challenged them to submit their patients to an examination of specialists representing the different branches of medicine, merely for the question of diagnosis. He staked his reputation for truth and veracity that the examination would reveal curable diseases, in many instances the cause of the insanity, the existence of the former never having been suspected by the alleged medical colossus who is known as the superintendent. The

evil he asserted was not a scientific one. It had passed beyond that point. It is now a problem in political economy, nothing more nor less than the eradication of the self-perpetuating scheme of superintendency, which is as pernicious as was ever priestcraft in its worst state.

A Certain Class of Obstetric Cases in Which the Use of Forceps is Imperatively Demanded, was the title of a paper by Dr. Augustus P. Clark, of Cambridge, Mass. If there is to be a resort to either the forceps or internal version, the former should be chosen. The former conditions thought to demand the use of the forceps, undue distance from the soft parts, great debility of the patient, and the occurrence of convulsions, fall far short of being the present status. When the head of the fœtus has descended into the cavity of the pelvis and the labor has become lingering from uterine inertia, the forceps may be used with great advantage. In protracted labor, when the fœtal head has engaged the pelvic brim, or has only reached that introitus and become arrested in its descent, the forceps should be preferred to all other means of relief. The necessity of the application of the forceps in such cases implies the normal or nearly normal proportion of the pelvic cavity. In cases of protracted labor where the head has not yet reached the pelvic brim, the fœtus still alive, his experience is largely in favor of the forceps. In every such case the forceps should be of requisite length and of a curve adapted to the peculiar curve of the pelvis. The frequent employment of the forceps merely for the shortening of labor, betrays lack of appreciation of the real advantages to be derived from instrumental interference, also want of conception of the dangers either immediate or remote which may follow in any case in which the forceps have been brought into requisition.

A New Forceps was Presented by Dr. L. E. Neale, of Baltimore. The pair of forceps which the doctor presented for the inspection of the Section had occupied his attention since 1886. The idea was a combination of the axis-traction forceps and the ones commonly in use. He claimed little originality in the instrument, it was simply the combination of the two varieties. The forceps had peculiar curvatures both pelvic and cephalic, and a peculiar basket and bulging shape of the inferior rib. The forceps may be used in all operations, and combines the utility of both varieties completely.

Axis-Traction and a Combined Axis-Traction Forceps, to be used as a substitute for craniotomy and version in pelvic deformities, were presented by Dr. T. J. McGillicuddy, of New York. He said the upper part of an infant's brain would stand considerable compression without injury. The base would not stand much. In this was seen the wisdom of encasing the latter part in a firm bony case, while the former was not so protected. He advocated his instrument as a substitute for craniotomy.

Dr. Chas. P. Noble, of Philadelphia, considered the subject of axis-traction forceps one of the most important which could be brought before this Section. The great merit of these forceps is that force is not wasted by dragging the head against the bony framework of the pelvis, especially the symphysis pubis. An unfortunate omission in Dr. McGillicuddy's forceps is that force is wasted in this way. This is not the case with Dr. Neal's forceps. Dr. McGillicuddy's forceps are similar to Huber's abandoned oues.

Dr. Joseph Hoffman, of Philadelphia, imagined that Dr. Neal's forceps, on account of the joint being so far removed from the handle, would be difficult to operate. He thought McGillicuddy's forceps immaterially different from those of Huber. These forceps do good work, but will fail in the lateral rotatory motion. Tarnier's forceps, though used to a certain extent in this country, are not used in Paris.

Dr. H. D. Fry, of Washington, hoped that Dr. Neal would make one more change in his forceps before he quit, as they made dangerous compression.

Dr. McGillicuddy answered that Huber's instrument had non-removable handles, and this was the reason it was abandoned. His forceps had removable handles.

Third Day, Thursday, May 7th.

The After-treatment of Cases of Abdominal Section, was the subject treated of by Dr. Charles. P. Noble, of Philadelphia. That which is accomplished in the after-treatment in abdominal section is principally of a negative character. The object is to protect the patient from all sources of danger while nature does her perfect work, sustain the powers of life, enable the patient to pass a crisis, to keep the emunctories active, and to prevent wound secretions from becoming a source of poison. Plenty of air, light, and ventilation. First twenty-four hours, give nothing in the way of food. Rinse the mouth with water, or if thirst excessive, enemas of equal parts of beef-tea and water. Second day, one or two drachms of water every half-hour. In thirty-six to forty-eight hours, one or two drachms of beef-tea at frequent intervals. If all goes well, on the fourth or fifth day water *ad libitum* may be given. After a week soft diet, and after two weeks a full diet. The drainage-tube used unless contra-indicated. It should be packed in sterilized cotton unless hemorrhage excessive, and a rope of gauze wet with bi-chloride passed down to the Douglass pouch and out to the cotton. In this way the most of the fluid is removed by capillary attraction. If hemorrhage excessive, it is better to use rubber dam about the tube. Surgeon should render his hands aseptic before handling the tube. The bladder should be emptied by the patient if possible. Care should be taken to avoid catheter cystitis. This is best accomplished by using a glass catheter. Bowels should be opened early, second or third day. The pain after abdominal section is largely intestinal, due to flatus or irregular peristalsis, and the best way to relieve it is to open the bowels. They should be kept open on alternate days during the convalescence. Thirst can often be appeased by bathing the hands in ice-water. Glycerine and ice-water will relieve dry mouth, but the sweet taste of the glycerine is objectionable to most patients. The patient should be encouraged to bear up under pain. Cotton wool pads and air cushions will add much to the patient's comfort. He keeps patients on their backs for two weeks, and out of bed after three weeks. Shock is best met by the application of external heat, the use of strychnia, caffeine, digitalis, and whiskey hypodermically, and decoctions of coffee or beef-tea hypodermically. If much blood is lost, large amounts of fluid will be absorbed from the rectum. A saline solution may also be injected into the areolar tissue. Vomiting from ether cures itself. If it continues more than two days some other cause must be sought. If simple means fail the vomiting will be found due to peritonitis or impending obstruction of the bowels. In either case the bowels should be moved at all hazards. When fever occurs the bowels should be kept frequently open and the body sponged frequently with cool water. The use of antipyretics is of doubtful value. When to reopen the abdomen and when to resort to medical measures is a difficult problem. In general, when the skin is dry, the face flushed, and the pulse full and bounding, secondary operation will be unnecessary. When the skin is "leaky," the extremities cool, the pulse rapid, and feeble absorption of septic material is going on, an operation is indicated. Opium in any form is unnecessary. Occasionally, in typical cases of abdominal section, morphia is useful when a nervous patient becomes excited and cannot otherwise be controlled. Asthenia must be combated by the systematic use of nutritive enema with whiskey, together with the administration of such liquid food as the stomach will bear. Champagne can often be given with advantage when other stimulants are rejected. Less can be done by alimentation and medication after abdominal section, to combat asthenia, than af-

ter other operations, because as a rule the stomach is not available.

Suggestions as to Abdominal and Pelvic Surgery, was the subject of a paper by Dr. William H. Wathen, of Louisville, Ky. The doctor thought there was too much laparotomy done and too many men doing it. The appendages are sometimes removed for vague nervous troubles, where there is no disease of the ovaries or tubes, or peritoneal adhesions. Such cases are often made worse, and mutilated in a way which cannot be corrected. Many of our best operators are urging upon the profession that the operation be not done unless there is well-defined disease, which has resisted, or will resist, other more conservative means. As the experience of an honest surgeon widens, he operates relatively less frequently, and he can recall cases which he does not believe should have been operated upon at all. In preparing for an operation, the physical and mental condition, and the hygienic and sanitary surroundings of every patient, should be made as perfect as possible, as without absolute surgical cleanliness septic infection may result. The danger from the atmosphere is practically nil, and the spray unnecessary, which, if strong enough to kill pathogenic germs, will be positively poisonous. If the operator neglects details he will be disappointed in the results Operating table has plate glass cover, and instruments which are used are placed in porcelain-lined vessels. Operator and chief assistants take a bath and put on clean aprons reaching from neck to feet. Towels washed and boiled, sponges clean and well-shaped, and after being well boiled are made aseptic after the method of Greig Smith. Sponges once used may be again used if again made aseptic in the same manner. He uses Chinese hard twisted silk of three sizes and sterilized, so that a culture cannot be made from it. All instruments, towels, etc., are washed thoroughly and then sterilized an hour before the operation. The patient is given one or more hot baths before operation, and the vagina and rectum washed out, and the pubes shaven. Before making the abdominal incision, the abdomen is again washed with soap and water and wiped off with sulphuric ether. Dry towels covered with towels wrung out of hot water are placed over the abdomen. He uses no antiseptic solutions for the sponges and instruments, but keeps them in sterilized water as hot as can be borne. Adherent intestines should be separated if possible, otherwise the operation is not a success. He believes antiseptics cause adhesions, and does away with them. The drainage tube should be used if hemorrhage has not ceased, or if foreign matter which is possibly aseptic is admitted into the abdomen. A small tube will usually drain as well as a large one. He does not favor capillary drainage of the tubes, nor vaginal drainage.

Report of a Case in which a Child's Arm Became Engaged in the Fenestrum of the Obstetric Forceps, was the subject of Dr. Dan Millikin, of Hamilton, O. The patient had borne four dead children after severe and complicated labors, each time under the care of a different physician. She had also borne one child living, which probably owed its life to the fact that it was very small and was probably prematurely born. The forceps were carefully applied, easily locked, and never inclined to slip. The effort to deliver by forceps was much prolonged. When finally it was attempted to deliver by podalic version a condition of affairs was found which to the essayist was unique in obstetrical practice. The upper blade of the forceps—that one which passed to the right of the woman's pelvis—would not come away. The lower blade was withdrawn first, but still the other would not come. The hand passed into the uterus revealed the fact that the child's right hand had passed through the fenestrum of the blade, and that in fact the blade hung on the bend of the elbow as a basket hangs on one's arm. The blade could not have been withdrawn without internal manipulation. Presently, when the child had been withdrawn by the feet, it was shown that violence had been done the arm near the elbow. No bones were broken, but the soft parts considerably injured. Undoubtedly, if the instrument had been long and stiff and it had been thought proper to compress the head, the arm might have been chewed off. Endeavoring to draw some warning from such a sorry job, we may note first, that the accident could only occur during the supra-pubic application of the forceps. All the evolutions it must have made to attain this position require room, and must have been made above the brim. In the second place, the accident cannot possibly be diagnosed unless the head and arm are so large as to arouse suspicion on account of the amount of substance between the blades of the forceps. In this case he did not believe that the most expert obstetrician could detect the accident before the attempted withdrawal of the instrument. For this reason he is ready to inquire whether the fenestrum has any right to exist. What is it good, for anyway? It has been said that the fenestrum gives lightness to the forceps. This is at first glance very plausible, but admits of question. We cut out the fenestrum, but we thicken the remainder of the blades. What signifies this weight, anyhow? Ordinary instruments do not weigh more than a pound, and the brother who cannot carry a pair or two of this weight is not fit to be out at night alone, much less use the forceps. The fenestra, it is said, permit of the forceps getting a better hold on the head by the protuberances projecting through them. This is seldom the case. Forceps rightly chosen and rightly used make room instead of occupy space. The fenestra increase the total amount of edge surface, which is an objection. Fenestra should at least be abandoned in forceps for use above the brim.

The Electrical Treatment of Fibroid Tumors, with an analysis of forty-six cases, was the subject of a paper by Dr. G. Betton Massey, of Philadelphia. He considered the rise and progress of the Apostoli method, and spoke of the unparalleled fierceness of the opposition to it, which was however as healthy as it was fierce. He did not regret this rivalry, but did regret the intemperate statements of certain extreme opponents, in striking contrast to many electro-therapeutists who willingly concede to surgery cases unsuited to electrical treatment, yet demanding active help. The doctor's results were as follows; 5 cases of complete anatomical and symptomatic cure, the tumor disappearing and the patient restored to health; 23 where the tumor was considerably diminished in size, and all other symptoms were cured; 8 in which the tumors were not diminished in size, but all symptoms disappeared; 2 in which the tumors were not diminished, nor the symptoms relieved. One case was made worse by treatment; 7 were not taken account of because two were polypoid, and their delivery only assisted by the electricity; and 5 cases were treated for too short a period. This gives about ninety-two per cent. successes, and eight per cent. failures. Of the five cases of complete cures by absorption, all were intra-mural and treated by intra-uterine application. Of the 23 cases symptomatically cured and anatomically reduced, 15 were intra-mural; 4, subperitoneal; 3, intra-mural and subperitoneal, and 1 submucous. Of the cases symptomatically relieved without anatomical reduction, 6 were intra-mural, 1 intra-mural and subperitoneal, and 1 submucous. He punctures only in a few cases to which it seems adapted. The intra-uterine method is certainly the method of choice.

While an increasing familiarity with hysterectomy for fibroid tumors will doubtless render operators more expert in the work, and possibly lessen some further the mortality of the operation, accurate knowledge is yet wanting concerning the after-histories of the cases reported as successful, with special bearing on the relief of painful symptoms, or their increase, by the addition of post-operative incidents or accidents. A conservative method of treatment which apparently acts by inducing retrogressive changes in the morbid process, resulting in a complete anatomical cure in over twelve per cent. and a practical cure in seventy-four per cent. of all cases, deserves most

careful consideration from scientific men, since but few remedial measures from analogous diseases can lay claim to an equal measure of success. The electrical method of arresting, reducing, and dispersing fibroid tumors, besides being truly curative in transforming vitiated tissue action into natural absorptive processes, has the further merit of leaving intact all neighboring organs and functions yet existing, as the ovaries, etc, the current acting as a general revivifier of all highly organized parts and processes, while hastening the destruction of adventitious and lowly organized tissue.

Papers relating to this subject were read by Dr. Marie B. Werner, of Philadelphia; Dr. Thomas Opie, of Baltimore; while the operative side was discussed in papers by Dr. Joseph Price, of Philadelphia, and Dr. Joseph Eastman, of Indianapolis. The discussion was conducted by Drs. Skene, of Brooklyn; Baldy, of Philadelphia; Fry, of Washington; Martin, of Chicago; Mordecai Price, of Philadelphia; Florian Krug, of New York; and Joseph Hoffmann, of Philadelphia. The discussion was a very long and interesting one.

The CHAIRMAN said he wanted the subject "peeled to the bone." He called alternately on advocates of electrical and surgical treatment. The statements on both sides exhibited more of a spirit of fairness, with less reckless utterances, than former debates during the past few years. It would seem that the surgical brethren are perfecting their technique, so that they are having better success and fewer deaths, and that the electrical brethren are doing the same thing; that surgeons do not operate on every case, nor do electricians, and on the whole we are coming to a more sensible view of the whole matter.

The Relation of Displacements of the Abdominal Viscera to Pelvic Disease, was the subject of a paper read by DR. J. H. KELLOGG, of Battle Creek, Mich. The purpose of this paper was to show by the study and comparison of the measurements of a large number of civilized women including peasant women of the laboring classes, Chinese, American Indian, East Indian women, and ancient Greek models. The doctor found: 1. That the average adult civilized woman of modern times is deformed, her waist measurement being too small for the rest of her body. 2. That this deformity, and others associated with or growing out of it, are the results of an unnatural and unhealthy mode of dress, and the neglect of physical or muscular activity. 3. That the deformity of figure which the average woman presents is indicative of changes in the static relations of the abdominal and pelvic viscera which are the source of many and serious morbid conditions and painful symptoms. 4. That in the great majority of cases of pelvic diseases in women, especially cases of displacement of the pelvic viscera, the pelvic disease is not an isolated or independent malady, but only a partial or local expression of a more general disease which involves also the abdominal viscera in whole or in part. 5. That in consequence of constriction of the waist and weakening of the lower muscles of respiration, the civilized woman has acquired an unnatural mode of breathing which tends strongly in the direction of the development of disease of the abdominal and pelvic viscera. 6. That any therapeutic method addressed to the cure of maladies of this class, to be successful, must include such measures as will correct the disturbed static relations of the abdominal viscera as well as the displaced uterus and ovaries, and will remove the cause of these displacements by restoring the natural supports. The doctor then presented the following measurements of the waist:

East India women of Telgu, whose clothing constricts the waist	40.6
English laboring women, brickmakers, who wear tight bands and heavy skirts	41.3
Civilized men, American	43.3
French peasant women	45.4
Chinese women	45.4
Yuma Indian women of New Mexico	55.2
The Venus de Milo	47.6

It thus appears that the average natural woman has a larger waist than the natural man, which is not surprising, since she has a larger liver, and her waist must sometimes expand still more to meet physiological requirements.

Tracings of the outlines of women were shown by the doctor. First was that of a healthy woman. The characteristics were a strong anterior dorsal curve, hips well set back, chest prominent, abdominal muscles well drawn up, head erect, and body well balanced upon the balls of the feet. In contrast to this was shown the unhealthy woman, who spends her time going from one gynecologist to another. Characteristics: hips forward, spine straight, abdomen pendulous, chest flat, shoulders drooping, chin projecting, body balanced upon the heels, and a weak and relaxed condition of the whole figure. In this case the stomach, bowels, kidney, and right liver were each several inches below their proper position. These constrictions of the waist cause unsightly protrusions of the lower abdomen. The doctor has made pneumographic studies of the breathing of several hundred women, including civilized, Indian, and Chinese women of various conditions. He finds women who have not been deformed breathe as do men. Chinese women and Indian women breathe as do men. A female dog breathes just as does a male dog. A man in a corset breathes as does a woman. A male dog in a corset breathes as does a woman in a corset. Hence the female type of respiration is pathological, not physiological.

NEW YORK ACADEMY OF MEDICINE.

SECTION ON SURGERY.

Stated Meeting, April 13, 1891.

WILLIAM T. BULL, M.D., CHAIRMAN.

Artery Forceps.—DR. A. M. PHELPS exhibited a modified artery forceps for operating in deep cavities and in tissues which were very much indurated.

Nephrotomy.—DR ROBERT ABBE presented a man on whom he had performed nephrotomy five weeks ago for symptoms of renal colic and hemorrhage coming down from the right ureter, as demonstrated by the cystoscope. These symptoms had lasted some years. The incision into the kidney revealed nothing, but at the pelvis a portion of the tissue felt gritty, and was scraped. The hæmaturia ceased within four days after the operation. The patient had no more pain, and had so far remained well.

DR. WEIR remarked that the Germans had recognized such cases; in some there had been found a slight irregularity of some nature, in others none, and they had called them cases of hæmophilia of the kidney.

Treatment of Hernia in Children by Means of the Hank Truss.—DR. S. E. MILLIKEN read a brief paper, descriptive of this method, and presented a number of children so treated (see p. 616).

DR. ABBE said he had some years ago been struck by the simplicity of this method of treatment, but had not succeeded so well as the reader. He was disposed now to try it again.

DR. DE GARMO sent a written communication, in which he deprecated a return to the crude means of the past for the treatment of hernia, which ought to receive the best management before the curative age had been passed. The hank truss might do in country practice, until time could be had for obtaining the rubber or celluloid truss, and while it might alone effect a cure, yet there were many cases in which it failed until the curative age had passed, as was shown in a number of patients thus treated at a certain institution in the city, who had finally wandered to his own clinic, perhaps too late for a radical cure. Nine-tenths of all hernias in children under five could be cured by a proper truss, but they must be kept under observation until the cure was complete.

The Curative Effect of Operations per Se.—DR. J. WILLIAM WHITE, of Philadelphia, read the paper by in-

vitation. It contained histories of a large number of cases reported in the journals and to him by letter, in which a surgical operation had been performed, nothing found or removed, yet the patients had been cured. He was led to study the subject by his experience with trephining for so called traumatic epilepsy, and finding nothing, the patients were still cured or much improved.

Classifying the cases roughly, they could be divided into three groups, according to the anatomical seat of the symptoms or supposed disease: 1, Operations for the relief of nervous phenomena, as epilepsy, insanity, paralysis; 2, operations for abdominal or pelvic troubles; 3, other cases.

He had time to read only a portion of the facts which he had collected on these three classes of cases. Regarding traumatic epilepsy, during the past five years he and Dr. D. Hayes Agnew had trephined in fifteen cases. Notwithstanding that in nine cases nothing abnormal was seen, all were immediately improved. In two there was no return of symptoms during the eighteen months and two years the patients remained under observation. Of fifty-six cases which he had collected of trephining for epilepsy in which nothing was found, thirty-five were reported as cured. There were some cases of cure of epilepsy following castration, stretching of the sciatic nerve, ocular tenotomy, etc. Professor H. C. Wood, having noticed epileptic attacks in a cat cease after a fall on the head from a height, had cured other domestic animals of epileptic attacks by striking them on the back of the head. The author had seen such benefit in epilepsy follow excision of scars in four cases, that he had thought it might be well to try simple excision of scalp cicatrices with the hope of effecting relief, if not a cure. He related a case in his own practice in illustration of cure of paralysis in some cases following operations upon the vertebral column, in which nothing abnormal was apparent.

The abdominal cases included a number of tumors, not excepting some said to have been of a malignant nature. The cure of tubercular peritonitis by abdominal incision was too familiar to justify reading his statistics on that subject. Briefly, he had collected one hundred and thirty-one cases treated in this way, with eighty-four cures, some improved. There was only one fact common to all, namely, that the abdomen had been freely opened, and a certain amount of intra-abdominal manipulation had been practised. In the majority of the cures no antibacterial agents had been employed within the abdomen.

The laparotomy cases included a number in which symptoms of renal calculi had disappeared, although no stone had been found in the kidney. Among the miscellaneous cases were several of cure of osteomalacia. He thought that a number of cures of different affections following ocular tenotomies were due to the operation per se rather than to correction of imperfect balance of the muscles. This was probably true also of some other operations, as circumcision in forms of paralysis, etc.

In attempting to explain these phenomena he had tried to formulate the conditions present in all or nearly all the cases. 1. Anæsthesia. 2. Psychical influence, or so-called mental impression. 3. Relief of tension. 4. Reflex action, or reaction of traumatism. These influences were operative in the majority of the cases

To test the value of an anæsthetic as a cure of epilepsy, he had tried the administration of ether simply, in a number of cases, but it had had little or no effect on either the severity or frequency of the epileptic convulsions.

Regarding psychical influence, if these cases had had hysteria, the cure could be understood, but only a small proportion of them were of that character. The epileptics were general epileptics; the tumors were palpable, visible, or both; the tubercular growths were verified. It might be assumed, then, that in at least two-thirds of the cases the symptoms were either associated with organic disease or with unmistakable evidence of organic disease. Was it possible for psychical influences to so change nutrition, or other conditions, as to lead to a cure of pathological states? He thought that a generally affirmative answer could be given. History was quoted to prove it. It must be admitted, however, that in his historical cases pain, and the personal equasion, were marked. It seemed only reasonable that emotional influences could influence morbid as well as physiological processes. Admitting the potency for cure of psychical influences, he said they were at present beyond our control, although they might become capable of future scientific employment. He then passed to the consideration of the possible effect of relieving of extreme tension, especially in abdominal cases.

Under reflex action he included traumatism, cauterization, etc.; it must be admitted that there was much of the reciprocal influence of one organ of the body upon others which we did not yet understand.

It seemed, then, that the anæsthetic had the least to do with effecting a cure in the cases under consideration; and that psychical influence, relief of tension, and reflex influence from traumatism had varying degrees of effect in different cases. The theory of accident or coincidence scarcely explained the facts.

Dr. Abbe thought that most of the tumor or tubercular cases of the abdomen owed their cure to the influence of irritation from manipulation. A number of other cases were to be accounted for on hysterical or psychical ground; perhaps some on bacteriological ground. He thought there could only be few cases in which the surgeon would be justified in undertaking an operation simply for the curative effects of the procedure, without removal of something visible.

Dr. Syms thought it was a little peculiar that twenty-five per cent. of cases of tuberculosis of the peritoneum should be cured by laparotomy, when opening of joints would not cure tubercular trouble there.

Dr. H. J. Boldt had been startled, as he supposed all had been, by the array of statistics brought forward by the author, but he thought we could not be too careful in accepting the statement that in a given case the cure was due to the operation per se. He did not believe that cases of malignant disease within the abdomen had been cured in this manner, although he had had two or more cases apparently of this kind himself. Doubtless there had been a mistake in diagnosis or other facts.

Dr. Thomas H. Manley said there was no doubt in his mind of there being a direct and positive connection between the mental and physical processes of life, between the psychical and the nutritive. He related the case of a girl, a sufferer from marked epilepsy, who ceased to have attacks following a fall over a rocking-chair.

Dr. B. F. Curtis expressed scepticism as to the diagnosis in at least many cases, especially those of malignant tumor within the abdomen.

Dr. R. F. Weir remarked that most of the cases which had been reported were peculiar cases, out of the way cases; therefore it was too much to assume at once that the cure was due to the operation per se. He had never seen tumors of the leg disappear in this manner. Why should they disappear when in the abdomen? There must be something peculiar in the make-up of the abdomen. This he admitted, there was the great sympathetic system, for instance. Here might be one explanation, yet an obscure one. The cases might be explained in the future on better ground than simply to say the cure was due to the operation per se.

Dr. J. D. Bryant rose to express gratification at hearing so exhaustive a paper, and mentioned a case of epilepsy cured by trephining, although nothing abnormal was found.

The author said a better title for his paper would have been, the possible curative effect of an operation per se.

The harvest for the young medical man is when the dispensaries close for the summer.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

THE PENDING DECISION AS TO THE RECONSTRUCTION OF THE UNIVERSITY OF LONDON—THE ANNUAL CONVERSAZIONE AT THE MEDICAL SOCIETY—SIR JOSEPH LISTER ON THE PRACTICAL ASPECTS OF THE COAGULATION OF THE BLOOD.

LONDON, May 9, 1891.

THE foremost subject of interest just now in medical circles is the question of the reconstruction of the University of London. At present that institution is unique as compared with the other universities of this country. It is in no sense a local university for London, as its name would imply, but is virtually an Imperial Examining Board which admits to its examinations candidates from all parts. There is, in fact, no restriction whatever as to residence and courses of study imposed in the faculties of arts, science, law, and music; candidates for degrees in these faculties may enter for the examinations whether they have studied at a college or not, and if successful at the examinations obtain their degrees. In medicine there is some limitation as to places of study, and certain courses of instruction have to be attended; but even in the medical faculty the degrees are not confined to London students, but may be obtained by provincial—and even foreign—students who have complied with the not very exacting conditions as to their courses of study. The degrees of the University have for some years past been open to women. No teaching is undertaken by the University, nor does it promote or endow research. It is purely an examining board, and the reputation of its degrees has been gained solely by the severity of its examinations. Its pass degrees, in fact, are admitted to be equal to the honors examinations of the other universities. London medical students, however, are placed at a grave disadvantage by this arrangement, excellent as it may be in some respects. No other British university admits to its degrees candidates who have not studied in one of its colleges. (Two universities admit candidates of mature age and long professional standing to their M.D. examinations.) A London medical student must consequently either graduate at the University of London or go without a degree. Only about ten per cent. of London medical students do obtain the London degree. In Scotland or the provinces—where there are local universities—a medical degree can be obtained on much easier terms, and the proportion of graduates to students is much higher. It has long been felt that in the matter of degrees London students are placed at an unjust disadvantage, and some few years ago a movement was inaugurated for the establishment of a new university in London which should combine the functions of teaching and examination. Stimulated from without, a movement began within the University for its reform, and several schemes were propounded in succession, only to be rejected by the various bodies whom it was hoped to conciliate. The latest scheme is to be submitted to the graduates on Tuesday next. It is in the nature of a compromise, but has been more favorably received by the various colleges than its predecessors, and the Senate regard it so hopefully that they have drawn up a draft charter embodying it. This charter will be presented to the graduates assembled in convocation, for their acceptance or rejection. They have the right to veto it, and between ten and eleven hundred graduates have already intimated their disapproval of it. Its fate is therefore doubtful. If carried, it will probably be only in consequence of the influence of the Senate and of the various teaching colleges interested. If rejected, we shall probably hear no more of the reconstruction of the existing University, but of the establishment of a new one for the metropolis on the lines of the older universities.

The Annual Conversazione of the Medical Society of London took place on Monday evening last. As usual on similar occasions science and amusement were pleasantly blended. The scientific part of the programme was the delivery of the Annual Oration by Sir Joseph Lister, who selected for his subject "The Coagulation of the Blood in its Practical Aspects." Thirty years ago, he said, Schmidt had come to the conclusion that fibrin did not exist as such in the blood, but that it was composed of two albuminoid bodies, viz., one in the liquor sanguinis (fibrinogen), and one derived from the corpuscles (fibrinoplastin). Many attempts had been made to ascertain the precise nature and mutual relations of the constituents of fibrin, and these investigations had somewhat overshadowed the question, which was more interesting to practitioners, viz., as to what were the circumstances which determined the mutual reaction of these two substances and the conditions under which the corpuscles parted with their fibrin-forming element to unite with the element in the liquor sanguinis. There was a wide difference in their relations toward the blood between the walls of the living vessels and ordinary solid matter. Drucke had concluded—as Sir Astley Cooper did before him—that this difference consisted in an active influence of the living vessels upon the blood, preventing it from coagulating. Sir Joseph said his own investigations had, on the other hand, led him to believe that the vessels were passive.

It had been objected to Schmidt's conclusions that hydrocele fluid and the allied effusions with which he operated were not strictly comparable to the liquor sanguinis in that they were transudations, and that the liquid had become altered in the process of transudation. Sir Joseph Lister then described an experiment which he had himself performed. In mammalia, he remarked, the blood soon coagulated after death in the larger vessels, but remained fluid in the secondary vessels for an indefinite period. Having removed a portion of the jugular vein of a horse, with the contained blood between two ligatures, he had suspended it in a vertical position. In the blood of a horse the red corpuscles behaved in a different manner to those of human blood or that of the ox. They fell rapidly and left the upper part of the blood relatively free from corpuscles. On puncturing the vein over the clear fluid the latter was found to be very slow in coagulating, and had only commenced to clot in about three-quarters of an hour; but a little of this fluid to which a small portion of coagulated blood was added clotted rapidly. Microscopical examination showed what was the cause of the coagulation, viz., the presence of some red corpuscles and of numerous white ones. If the corpuscles could have been absolutely separated there would have been no clotting, and yet the plasma had not been changed by transudation. Sir Joseph said it seemed to him evident that Schmidt's conclusions were essentially right. He then described an experiment which he had performed, and which consisted in passing some blood from an excised jugular vein (from an ox) into a glass tube with the least possible disturbance. After ten hours the blood was still fluid, with the exception of a crust of clot lining the wall of the vessel, and he thought this was evidence that the blood has not a spontaneous tendency to coagulate even when not kept in check by any action on the part of the living vessels. This conclusion had since been confirmed by more than one observer, and notably by Benjamin Haycroft, who had found that if blood were dropped into a deep jar of castor-oil, and the drop kept from coming into contact with the walls of the jar it remained fluid. This experiment was even more satisfactory than his own, inasmuch as no coagulation at all occurred. It had also been shown that neutral gases—such as oxygen and nitrogen—were incapable of inducing coagulation, and Mr. Haycroft's experiments showed that this was the same with chemically indifferent fluids. In its relation to the coagulation of the healthy blood the wall of the healthy blood-vessel resembled the particles of an indifferent fluid;

when, however, the living tissue was damaged and its vitality impaired, it then behaved like an ordinary solid. This was the case not only when the vessel was wounded, but also when it was subjected to some influence calculated to impair or suspend its vital activity.

He had come to the conclusion that the undisturbed coagulum resembled living tissue in relation to coagulation, viz., that it did not induce coagulation in its vicinity. In an amputated limb we found clot where the veins were wounded by the knife, but not elsewhere. Yet in his experiment with blood contained in the jugular vein of a horse the clot did propagate itself so that at the end of two days what had been merely a crust had become a thick clot, though there still remained in the middle a small quantity of liquid uncoagulated blood. He thought at the time that this extension of clotting was due to some imperfection in the manner of performing the experiment, but he was now inclined to think that the fact admitted of another explanation. Schmidt had found that the fibrino-plastic substance derived from the corpuscles was vastly in excess of what was required to induce coagulation. This was illustrated by the fact that the serum which was expressed from the clot would set up coagulation if added to hydrocele fluid. This being so, and seeing that ordinary blood-clot was continually shrinking and squeezing out serum containing the fibrino-plastic substance, it could readily be understood how in such an experiment the clot first formed squeezed out serum which combined with the fibrinogen to form fibrin. Under such circumstances it was easy to understand why the clot should extend, but why should it not do so in the living body? Why did the clot not spread from the injured vein after phlebotomy? He thought this must be explained by a fact to which he had already alluded before the Society, viz., that on letting blood from a horse, with antiseptic precautions, into a flask which had become superheated to destroy any micro-organisms, although the blood coagulated in the flask yet the clot did not shrink, and there was not a drop of free serum, although the preparation was kept for many days. It seemed inconceivable that this should be due to the destruction of the micro-organisms, but the same result followed the letting of blood into a jar which had been purified by a strong solution of corrosive sublimate. The same effect obtained by two such different means certainly seemed to point in the direction of the organisms having something to do with it. This explanation accounted, at any rate, for the extension not taking place in the body. It meant that the clot formed in the body did not shrink, and so the serum was not squeezed out to set up coagulation in the adjacent blood. This might not be the correct explanation, but it was a possible one. This immunity from extension, however, only applied to the uninjured blood-clot. In a traumatic aneurism the constant pressure of the blood on the clot caused it to extend. When an artery was tied in its continuity the clot was usually firm enough on the proximal side where the heart-beat disturbed it, while on the distal side it was apt to be very imperfect. This was further borne out by the fact that secondary hemorrhage was far more frequent on the distal side. The same thing was observable in venous aneurism, the pressure of the blood leading to the formation of sufficient clot to organize.

The orator said that while he did not believe that the living vessels possessed any influence to prevent the coagulation of the blood, it was evident that there must be this inhibitory power somewhere, for otherwise coagulation would inevitably follow transfusion. He presumed that this inhibitory power resided in the capillaries. We could not otherwise say why the blood did not coagulate in the frog's capillaries when congestion and exudation were induced. The capillaries must possess the power of preventing or inhibiting this action of the fibrino-plastic substance, which was certainly present under these conditions.

IS THE CONTAGION OF TYPHUS ALWAYS IMPORTED?

To the Editor of the Medical Record.

Sir: My apology for this paper is that others like myself sometimes meet with a fever which does not present the characteristic symptoms of our well-described fevers, unless typhoid fever is in these cases returning to the typhus type, and to essay to do away with the common impression that the germ of typhus fever is always imported.

There was editorially noticed in the Medical Record, April 18, 1891, a death from typhus in the New York Hospital, in the person of a poor Hungarian, who had only been in America two months, and the journal stated that he doubtless brought the infection from Hamburg. If this case of typhus was contracted in Hamburg, then the period of incubation was much longer than I have seen a record of.

In the latest edition of "Flint's Practice" is the following: "In 1841 I reported four cases of typhus developed in the Erie County Almshouse. They occurred during the winter months. The wards in this institution were quite small and crowded, and for the sake of warmth fireplaces, which had previously been used, had been bricked up and close stoves substituted. There was an abundant eruption in all these cases, and an examination after death in the only case which proved fatal showed the absence of the typhoid lesions."

In these cases overcrowding and want of ventilation seemed to be important elements in causation. No cases of typhus occurred out of the Almshouse, and the disease was not imported.

Various names are presumably given to this disease in America, such as anomalous fever, mild typhoid, bastard typhoid, typho-malarial, septic, or nosocomial malarial, and innominate. Are not these but roses by other names? Why may not the germ or germs of typhus also originate in America, where, at times, there are three millions of paupers, and why may the germ not continue to originate? We have the same conditions in many of our large cities, villages, and at other points which obtain in those great endemic centres, Ireland, Italy, and Russia. The pent up air of a ship or jail is not worse than the air in a sleeping- or work-room, 12 × 12, with windows down, doors closed, containing six people, some of them menstruating, and a closed stove. Yet in cold weather, in certain places in our country, this condition of herding can be seen, coupled with a lack of variety in food.

I have seen no record that typhus has appeared in the Mississippi Valley and the States bordering on the Pacific Ocean, neither is it indigenous to such countries as Australia and New Zealand. Why? Because there are no considerable cities in the Mississippi Valley north of latitude 40° in which there is much poverty and squalor, and the climate inspires to labor. The climate of the Pacific coast and the general wealth of its people does not compel them to use closed stoves for seven months in the year, to overcrowding, and their diet is most varied.

In Australia and New Zealand the people must avail themselves of fresh air, and so in all tropical, subtropical, and southern climates. Besides, they have in their fresh fruits a prophylaxis against typhus and such like fevers.

Undoubtedly the lack of proper food and of pure air are two of the factors in the causation of typhus, poverty and cold weather are auxiliaries.

Our native typhus is milder than the imported, for the reason that blood filled with the extracts from good food, and kept warm, is more resisting than blood filled with the waste products of potatoes, polenta, and potato whiskey, and exposed to cold. It is not so contagious. The eruption in our typhus may be frequently absent, but it may be present in the axillæ, or so sparsely scattered over the extremities as to be overlooked. Typhus is allied to scurvy, hence we should not expect much eruption in a case of typhus in a well-fed American, and with attention to ventilation and isolation, we should expect him to re-

cover. Neither does the temperature range so high for the same reason, but the rapid pulse and rapid respiration is similar to the foreign typhus.

In illustration I will report fifty-two cases of a fever which had so many points of resemblance to typhus that I ventured to call it typhus. I very much regret that no autopsies were made, which might have definitely settled the question, but not necessarily.

In the last week of July, 1880, my partner, Dr. F. T. Fry, and myself commenced to attend some fever patients at Quinnimont, W. Va., which was a mining and manufacturing town in the mountains, on the C. & O. R. R., with a population of about three hundred. Quinnimont comprised three villages; one was at the depot, one three-quarters of a mile from the depot and nearly on the same level, and one was situated upon a high mountain, about fifteen hundred feet above tide-water, two miles and a half from the depot. The disease commenced in the mountain village, in the person of an Irishman, aged twenty-five.

He had been living in the village several years, and seldom left it.

His condition on the morning of the sixth day of his illness was as follows: Temperature, 103° F.; pulse, 108; respiration, 36, and his clinical history for the most part was the same as the clinical histories of the majority of the cases. No abdominal symptoms of typhoid fever, either internal or external; face congested; sweats some; tongue coated in the middle, red at the tip and edges; muscular tremor; some delirium in the evenings; hair did not fall, nor were the finger-nails much affected during convalescence. The access was sudden; the patients were seized with a chill, followed by moderate fever, headache, pains in the back and extremities, and great weakness.

I will now detail a circumstance which may bias my ingenious reader as to causation.

Soon after the Irishman fell ill a public school for white children, within a short distance of the Irishman's house, and on the edge of a graveyard, was broken up by the fever, the teacher, a young man, and many of the scholars suddenly becoming ill. Within a few feet of this school-house a negro man had been buried on July 1, 1880, and in investigating the epidemic I saw common house-flies (not the blue fly, the scavenger *par excellence* of decomposition) on his grave early in the morning, when the temperature was probably below 50° F. It was disagreeably cold; but upon putting my nose near the mound I could not detect any odor; but gas may have been present. This man had died from a gun-shot wound of the abdomen, and we had held an autopsy. He was buried in a defective coffin, and probably in a too shallow grave.

This circumstance might suggest the Oriental plague, to which typhus has analogies—the peculiar burial of the Copts is alleged to be the sole cause of the plague.

But after much study I could not satisfy myself with any theory as to causation or spread of the epidemic. There was no common source of water or milk supply, and no sewers. These people were crowded in small and filthy cabins, the miners sleeping upon bunks, the bunks in tiers; the little windows and the doors were closed at night to keep the cold air out. The white portion of the population were first affected, and the disease lasted a month, sparing no ages except probably the extremes. The average time in bed was a week.

Of the 52 cases 23 were white females, 15 colored males, 8 white males, 6 colored females. The reason why so many white females were affected was because the majority of them were crowded in two small boarding-houses.

The highest rate of pulse in each of 23 cases was 120 and above, and in 3 cases it was 144. One of the latter, a male negro, died. The lowest rate was 84. The highest temperature was, in 1 case, 104° F., and in 4 cases not quite 104° F; the lowest, 97.5° F., reduced by perspiration. The respiration in 5 cases was 48, the average rate, 36. Eight cases had epistaxis once or oftener, 1 nearly dying from this cause. One case had a profuse hemorrhage from the bowels. Three cases had slight diarrhœa, but constipation generally existed. The tongues of all were coated, and red at the tip and edges; some were moist and coated whitish, others yellowish; some, in the latter days, were dry and fissured; oral catarrh, including scorbutic gums, existed in some, and also glossitis. One case, a young lady, had petechiæ upon abdomen, 2 cases sudamina, and 1 had retention of urine after he had been sick a few days. In 1 case there was a relapse.

There were a few cases in the other villages, but almost without exception these persons had contracted the disease in the mountain village. There were 2 deaths: 1, a Scotch girl, about ten years of age, and 1, a young negro man, who became delirious before death. Both died in the mountain village.

Treatment: Ventilation, diet, mineral acids, and especially phosphoric, with tonic doses of quinine and stimulants.

We should have said above, in confirmation of our opinion, that Niemeyer wrote that "small epidemics of exanthematic typhus are occasionally seen almost everywhere; and may usually, but not always, be traced to contagion." And if such is the case with the exanthematic form, why may it not be with the American form, which often is devoid of the exanthem?

T. R. Evans, M.D.

Loudon County, Va.

Army News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from May 17, 1891, to May 23, 1891.

Skinner, John O., Captain and Assistant Surgeon, Fort Davis, Tex. Will proceed at once to Fort Clark, Tex., and report to the commanding officer for temporary duty. S. O. 44, par. 4, Department of Texas, May 13, 1891.

McCreery, George, Captain and Assistant Surgeon. By direction of the Secretary of War, is relieved from duty at Fort Clark, Tex., and will report in person to the commanding officer at Fort McIntosh, Tex., for duty at that post. S. O. 114, par. 4, A. G. O., Washington, D. C., May 19, 1891.

Banister, William B., Captain and Assistant Surgeon. Assigned to duty as Medical Officer with Troop B, Sixth Cavalry, while en route from Fort Myer, Va., to Fort Washakie, Wyo. On arrival of the troop at its destination, Captain Banister will return to his station at Washington Barracks. S. O. 104, par. 3, Division of the Atlantic, May 20, 1891.

Woods, Marshall W., Captain and Assistant Surgeon. Granted leave of absence for one month, to commence on or about the 23d instant. S. O. 104, par. 1, Division of the Atlantic, May 20, 1891.

Lippitt, William F., Jr., First Lieutenant and Assistant Surgeon. By direction of the Secretary of War, will report in person for duty to the commanding officer at Fort McPherson, Ga. S. O. 115, par. 7, A. G. O., Washington, D. C., May 20, 1891.

Brooke, Benjamin, First Lieutenant and Assistant Surgeon. By direction of the Secretary of War, will report in person for duty to the commanding officer at Fort Riley, Kans. S. O. 115, par. 7, A. G. O., Washington, D. C., May 20, 1891.

Ireland, Merritte W., First Lieutenant and Assistant Surgeon. By direction of the Secretary of War, will proceed from Columbus City, Ind., to Jefferson Barracks, Mo., and report in person for duty to the commanding officer of that post. S. O. 115, par. 7, A. G. O., Washington, D. C., May 20, 1891.

IS EMBRYOTOMY OF THE LIVING FŒTUS JUSTIFIABLE?[1]

BY EGBERT H. GRANDIN, M.D.,

CHAIRMAN OF THE SECTION ON OBSTETRICS AND GYNECOLOGY, NEW YORK ACADEMY OF MEDICINE, ETC.

OF all the problems in obstetrics, the one propounded to-night is the most vexed, and the most important as well in the light of the marvellous progress of abdominal surgery during the past decade. Every physician whose practice necessitates attendance on woman during the supremest of her trials, when confronted by the necessity of destroying the lesser human life in order to succor the greater, must have felt instinctive repugnance; and every physician will hail with joy the advent of the day when the call for fœticide no longer exists, in that, through resort to the Cæsarean section the babe may be saved, and yet the mother not imperilled.

Ten years ago the answer to our question was necessarily affirmative. The maternal mortality from the Cæsarean section at that time was about forty per cent., on an average, hence absolutely no regard could be paid to the life of the fœtus. To subject the mother in those days to the Cæsarean section, except under stringent absolute indication, meant death to her, and with no certainty of saving the child. Ten years ago cleanliness, to say nothing of antisepsis, was an almost unknown quantity in obstetrics; the proper method of suturing the uterine wound to guard against gaping and internal hemorrhage was as yet only on the verge of evolution; the peritoneal cavity, if not a *terra incognita*, was with the vast majority of men a *nolle me tangere*; septicæmia was rife in our maternity hospitals. What wonder, then, that embryotomy was a beneficent necessity, and the Cæsarean section, particularly a successful one, was a *rara avis*. To-day our knowledge and our results are very different. Septicæmia during the puerperal state means simply faulty technique in the conduct of labor. The mortality from this cause has fallen as low as one-quarter of one per cent. in our New York maternities. To-day we know how to effectively suture the uterine wound; to-day we do not fear entering the peritoneal cavity, saving many a life which formerly was doomed. The abdominal surgeon is prepared with his statistics of series after series of laparotomies, complicated and uncomplicated, with, in individual instances, a mortality of from one to five per cent. Enormous fibroids of the uterus are removed without an untoward after-symptom—an operation, let it be remembered, for the removal of a tumor which of itself rarely kills and retrogrades at the menopause. In the face of all this, the time is certainly ripe for frequent discussion of this question of embryotomy. We may not solve our problem just yet in the desired direction, but, if I mistake not the signs of the times, the absolute certainty in the near future is that the physician will not be justified in sacrificing the living child because the maternal chances from the Cæsarean section are unfavorable. Modern methods of asepsis, and modern methods of operative procedure, are yielding results which will shortly prove that the only risk to which the Cæsarean section subjects the mother is shock. This factor, it must be granted, is associated to an equal degree with any and all of the methods which are at our disposal for the sacrifice of the child.

Aside from the operator himself, there are certain factors which militate against the relegation of embryotomy to its proper sphere—instances where the fœtus is dead.

One factor, and a prominent one, is the lack of thorough education in obstetrics. Midwifery must be raised to a higher plane than it has as yet secured. While the art can never become a specialty, greater stress should be laid on its practice in our medical schools. The student should be told that in no given case can it be predicated that nature will be equal to her task. He should be told to make it his rule in practice to examine every woman he is engaged to confine, in order to determine the configuration of her pelvis, and in order to estimate the probable size of the fœtus which must pass through this pelvis. Pelvimetry has with us been too much neglected, with the result that over and over again the forceps and version are resorted to in instances where accurate pelvic measurement would teach that both are contra-indicated, from the side of the child as well as from that of the mother. The result of faulty methods of instruction, the result of blind obstetrical practice, have been most disastrous in our statistical data. Not alone have children been sacrificed, but women also, in instances where a sounder scientific training would have taught that the Cæsarean section carried with it no greater risk to the mother, and offered hope of saving the life of the child. We must learn, then, to deliberately *elect* the Cæsarean section. This accomplished, we will cease mutilating children, a procedure which everyone who has been called upon to perform, will admit is repugnant to his very nature.

I will not dwell at length on the moral side of this question of embryotomy. Theologians cannot decide it for obstetricians. "If you cannot extract the child without killing it, it is murder to kill it," is the edict of the Church, easy to pronounce by those who are never called upon either to extract or to kill; but it is an edict which could carry absolutely no weight with the obstetrician so long as the alternative of not killing the child was the death of the mother. We must view this question purely from a scientific standpoint, and criticise it in the light of established scientific facts. Such at least is the state of the question as far as the physician is concerned. With the laity the question is a very different one. If the solution of our query is to be left in the future, as it has been largely in the past, to the relatives of the fœtus the fate of which is at stake, embryotomy of the living fœtus will always remain a justifiable procedure. The layman does not care for scientific facts, and throws statistical data to the wind where there is a choice between embryotomy and the Cæsarean section. He will insist to-day, even as he always has, on the sacrifice of the child rather than that the woman should be subjected to an operation which in the popular mind carries with it almost certain death. As for the woman, it will be rare indeed that the maternal instinct is strong enough to enable her deliberately to select the Cæsarean section in order that her unborn babe may have a chance of life. The point, then, which we as physicians will have to face sooner or later, is: Should the laity have any voice in the decision whatsoever? As physicians, we are not to weigh the relative value of one life over the other. We are called upon simply to do our best by the two lives committed to our charge, and if we can once deliberately conclude that the Cæsarean section carries with it but slight, if any greater, risk to

[1] Read before the New York Academy of Medicine, April 16, 1891.

the woman than does embryotomy, then it becomes at once our duty to elect the operation. Let me state distinctly what I mean by the term *elective* Cæsarean section. To take a concrete case: I am asked to attend a woman in her approaching confinement. I find on inquiry and examination that she is within a few weeks of term. External pelvimetry teaches me that her pelvis lacks the normal configuration. Internal pelvimetry shows shortening of an inch and a half to two inches in all the diameters, or possibly only in the true conjugate. By means of external abdominal and combined abdomino-vaginal examination, I determine that the fœtus is probably of average size. Attempts at causing the presenting part to engage in the brim of the pelvis by means of downward pressure on the uterus suggest to me that this presenting part cannot readily enter the pelvic canal. I feel, therefore, that the chances are against the birth of a living child, either through the efforts of nature or resort to forceps or version. I at once begin to prepare the patient for Cæsarean section, even as I would were the intended operation an ovariotomy. I clean out the intestinal canal; by means of daily baths I obtain ample function of the sweat-glands; I have the room where the operation is to be performed thoroughly cleaned; I select the day and hour for the operation, placing it as near full term as is possible; about six hours before the operation I induce labor by one or another of the recognized methods, operating therefore under the best obtainable conditions. This woman's chances of recovery, it seems to me, are absolute, barring that bugbear of all surgery—shock.

In this suppositious case, I have selected, it will be noticed, an instance of slight pelvic deformity; and further, the pregnancy has already advanced too far for anything to be gained by the induction of premature labor. I take it for granted that all will accept the Cæsarean section under the absolute indication, that is to say, where the true conjugate measures less than two and one-half inches; I further concede that where the case is seen early enough, the induction of premature labor should always be elected. Now, in this same case, can I or will I elect to perform embryotomy? No, but having first given nature a chance, I will resort to the forceps or version, or to both; and finally, these failing, perform what may turn out to be a very difficult craniotomy. The already exhausted woman is subjected to the further exhaustion which is associated with a protracted embryotomy; further, she is subjected to the risk of deep cervical rupture with profuse hemorrhage; further still, there is risk of uterine rupture, to say nothing of fistulæ or deep laceration of the pelvic muscles and fascia, which form wide avenues for the entrance of the pathogenic germ. Is the woman's chance of recovery as great as if I had deliberately elected the Cæsarean section? These companion pictures are from life. I have seen deeper shock after embryotomy than after the Cæsarean section; I have met with profuse hemorrhage after craniotomy; I have yet to witness sepsis after either, and I have yet to lose a case from cause directly traceable to the operation after either. But my experience with both operations has caused me to waver somewhat from my early training, and has led me to formulate for myself the following rule of practice, in which I believe the results in the next few years will justify me: In hospital practice I shall urge, and where possible perform, the elective Cæsarean section in suitable instances under the relative as well as the absolute indication: In private and consulting practice, I shall urge the section under similar indication, although I know that, for the present certainly, the advice will rarely be accepted. And why? Because of that fallible test upon which we are all too prone to ultimately rest—statistics.

I have hitherto absolutely ignored the statistical data at my disposal, for the reason that they give no fair estimate of the results obtainable after the elective Cæsarean section. If we take the statistics as collected by Harris, of Philadelphia, we find that the improved Cæsarean operation has saved nearly seventy-six per cent. of the women, and nearly ninety-four per cent. of the children. The fallacy of these data as giving us a clue to the obtainable results from the operation I have pleaded for, is the fact that we do not know in how many of the instances the operation was deliberately elected. If the cases were thus sifted I question if the maternal mortality might not be lowered beyond ten per cent. I so judge from the records of individual operators. There are German operators whose mortality is as low as six per cent.; Hertsch has recorded seven cases with no deaths; Cameron, of Glasgow, ten cases with one death; at the New York Maternity Hospital the record for the past two years is four cases, all successful both as regards the mothers and children. In the same hospital, during this period, there have been performed four craniotomies with one death, and in another case the shock was so extreme for hours that the patient only rallied after resort to transfusion. On the other hand, the mortality after embryotomy in the European maternities has varied from five and one-half per cent. to forty-five per cent., according to the degree of pelvic contraction in the presence of which the operation has been performed. Obviously, the maternal mortality after embryotomy cannot fairly be juxtaposed to that after the elective Cæsarean section, for the very reason that, except in extreme degrees of pelvic contraction, destruction of the living fœtus will always remain, so long as it exists as a justifiable measure, a matter of last resort. The point I desire, however, chiefly to emphasize is, that the statistical data at present at our disposal give us absolutely no omen of the future status of the elective Cæsarean section. If those of us who are connected with maternity hospitals will only, with one accord, cease resorting to embryotomy except in instances where, for one or another reason, the woman's condition does not warrant the section, I have little question but that the results will soon prove that the safety of the mother is not imperilled by the deliberate selection of the alternative operation which avoids mutilation of the child.

NOTES ON THE THERAPEUTIC USES OF ARISTOL.

By DANIEL LEWIS, M.D.,

SURGEON TO THE NEW YORK SKIN AND CANCER HOSPITAL.

The claims which have been made for aristol in surgical practice, as well as in dermatology and dentistry, have been so often repeated by numerous authors as to indicate valuable therapeutic properties. It is not my purpose to review what has already been reported, but simply to offer a few notes regarding the results of its employment in my service at the New York Skin and Cancer Hospital, as well as in private practice.

The following preparations have been employed: Powdered aristol; aristol and iodol, equal parts; ointment of aristol and vaseline, 4 to 30; aristol gauze, moist and dry; solution of arstol in albolene or benzoinol, 4 to 30; solution of aristol in flexible collodion, 1 to 30.

The pure powder has been applied to the surface of an ulcer following the slough of a flap after removal of a cancerous tumor of the abdominal wall. The purulent discharge was very copious and offensive, the patient suffering from septicæmia in a marked degree before operation. The offensive odor was promptly corrected by the use of the powder, which was dusted thickly over the surface, and the discharge checked within twenty-four hours after the dressing was first applied. In this particular instance the dressing was changed to the ointment of aristol and vaseline, as the powder proved too dry an application. It was evident, however, that for checking suppuration the drug possessed powers superior to iodoform or any of the other preparations usually employed for that purpose.

In other and similar ulcerated surfaces, where healing under a scab is desirable, or rather unobjectionable, the powder formed a crust under which the granulations were healthy and sufficiently rapid. So far as I can judge, it possesses no specific alterative action upon malignant tissue, although my experience in that class of cases is not sufficiently extensive to warrant a denial of the cures claimed for it in epithelioma of the skin.

A most satisfactory result of the use of aristol powder was obtained in a number of cases of ulceration (non-malignant) of the cervix uteri. It was applied by means of an ordinary cotton tampon, smeared with vaseline, to which the powder adhered, then placed in position against the ulcer, and left from forty-eight to seventy two hours. Induration, thickening, and suppuration were all promptly improved, and the ulcers, which had resisted prolonged treatment by glycero-tannin, borated solutions and other applications in common use, finally healed. In no case was any irritation excited by the remedy itself, the stimulating effect corresponding in degree to that of tincture of iodine used in similar cases.

Another application in these cases, which is convenient and efficacious, is a mixture of aristol and iodol in equal parts, applied through the speculum by an ordinary powder blower, after which a light tampon of absorbent cotton may be inserted.

The same mixture has been employed in quite a large number of cases of chronic nasal catarrh, where the discharge was profuse or fetid, and when employed twice a day, improvement was marked and permanent. The aristol renders the iodol lighter and more easily used by the insufflator. The same absence of all irritation due to the drug, or any other disagreeable consequences, was as marked in these nasal cases as in the uterine diseases already mentioned.

The ointments of aristol, composed of vaseline or cold cream, are capable of wide application in all skin affections which show a tendency to pus formation, or where a mild stimulating effect is desirable. They may be used with equal success in fresh wounds which are left to heal by granulation, but my judgment is that a larger percentage than four to thirty must often be employed in such cases. A more desirable dressing after surgical operations is now supplied in the moist gauze, such as is manufactured by Schieffelin, upon which an additional quantity of the powder may be sprinkled when desired.

The petroleum preparations, albolene and benzoinol, are solvents of aristol, and form a neat and satisfactory dressing in many cases where moist applications are required. These solutions have been recommended where gangrene was threatening or already commenced, and in a case of that kind, after a phlegmonous erysipelas of the leg, plain gauze saturated with these and packed over the limb was exceedingly satisfactory. In some instances these solutions were found to be useful uterine and vaginal dressings instead of the more common applications.

One of the most valuable of all the aristol preparations, on account of its extensive application, is the preparation of aristol in flexible collodion. The ether is such a perfect solvent of the drug that the preparation is really an elegant one. In the first place, any abrasion of the skin on the hands of the operator may be dressed with this before commencing operations. The line of sutures is rendered impervious to air, and consequently infection from without, by being covered with a coating of this preparation. Here, as in other external cases, the absence of offensive odor and of any tendency to irritation places its utility far above the iodoform collodion which has been so generally employed for this purpose.

Recently I have employed it in the treatment of hyperidrosis of the palmar surfaces. A child, who had been unable to attend school because she could not hold a book in her hands without spoiling it, was relieved of all disagreeable symptoms by its use in a very short period.

No class of cases, however, have given greater satisfaction under this application than erysipelas in its early stages. A patient who was septic previous to operation for the removal of a malignant tumor, developed a decided erysipelas of the face the second day after the operation. One cheek, external ear and side of the nose was invaded during a single night, while the patient's temperature rose to 102° F. The inflamed surface and a little distance beyond it were painted with a thick coat of this aristol collodion, and the disease was immediately and entirely arrested. The coating was left in position four days, when it was easily removed, and there was no recurrence of the disease about the face. A few days later a similar inflammation developed near the seat of operation, and the chest-wall was painted in the same manner with equally good results An old gentleman, aged eighty-nine, was treated for an epithelioma of the external ear by Jenning's paste of caustic potash, vaseline, and cocaine, and two days afterward had a severe chill, followed by a temperature of 102⅘° F., and the entire external ear, malar region, and lower lid were involved in an acute erysipelatous inflammation twelve hours afterward. The disease had also shown itself over the eyebrow on the same side. A single application covering the diseased surface arrested all further spread of the disease, and three days afterward he was perfectly well, and granulations proceeding satisfactorily at the point of operation. I have often employed flexible collodion in facial erysipelas, and find it a satisfactory remedy, but in these instances it seems certain that the aristol acted as a disinfectant which was exceedingly prompt in its action, and more effective than any other application I have ever employed, not excepting the white lead paint which Mr. Barwell, of Charing Cross Hospital, has found so useful, and whose experience I have often verified.

We have, then, in the cases mentioned, a drug which is safe, agreeable, cleanly, and efficacious to such a degree as to render aristol one of the most valuable additions to our therapeutic agents which has been presented to the profession during recent years.

249 Madison Avenue.

THE DIAGNOSTIC VALUE OF VOCAL FREMITUS IN PNEUMONIA.

By J. P. RAND, M.D.,

Worcester, Mass.

About a year ago I had a case of pneumonia following la grippe in which the evidence of consolidation was very marked. The percussion-note was dull, almost flat, upon the anterior chest, so that I half-suspected pleuritic effusion might be present. But the ear could detect some respiratory murmur upon the back, and marked bronchophony and bronchial breathing in front, while change of position produced no change in the location of dulness; and yet when I sought by palpation to corroborate my diagnosis by increased vocal fremitus, I found it almost entirely wanting. I was puzzled at the contradictory evidence of the physical signs, for I had always been taught that vocal fremitus was increased in pneumonic conditions of lung tissue. I looked up the authorities. Loomis says, "Increased vocal fremitus occurs in those affections in which lung tissue becomes more or less solidified, as in tuberculosis, pneumonia, pulmonary apoplexy, and œdema of the lung." Again, under the physical signs of first stage of lobar pneumonia he says, "There is more or less marked increase in vocal fremitus over the affected lung; the degree of increase corresponding with the extent of the congestion." Under the second stage he says, "There is usually marked increase in the vocal fremitus over the consolidation. In some instances this is so slight that no difference can be detected; very rarely it is less than on the normal side." And under the third stage he says, "Vocal fremitus gradually diminishes." Flint says, "Increased vocal fremitus generally accompanies vocal resonance, and it

denotes solidification of lung." "Diminished or suppressed vocal fremitus is valuable in the diagnosis of pleurisy with effusion, empyema, hydrothorax, and pneumothorax."

Dr. J. Graham Brown, of Edinburgh, in his "Medical Diagnosis," page 142, says, "When infiltration takes place into the air-cells of the lung the pulmonary parenchyma becomes at once a better conductor of the vocal vibrations and in consequence the thrill becomes intensified. Such is the case, for example, in lobar pneumonia." "The fremitus is likewise increased where there is phthisical consolidation, particularly where cavities are formed."

All these authorities say that there may be cases of extreme consolidation in which fremitus is diminished or absent. Now, while I do not feel myself competent to contradict the teachings of our greatest physicians, in this particular my observations and reason lead me to doubt their correctness. In medicine as well as theology we accept too much and think too little. We are told in certain diseases such and such conditions obtain, and having made up our minds that the disease exists we look, and behold the conditions. In other words, we make a diagnosis from the history or appearance of the patient, perhaps in pneumonia from the very characteristic sputa, and presently we perceive all the physical signs described in the book as belonging to the disease. No matter how absurd and contradictory, how false and unscientific, we see them just the same, and thus year after year the fallacy is perpetuated.

I once read a story of certain accomplished knaves who manufactured a magic dress for an ancient king and claimed for it a marvellous power of detecting fraud, since any who were unable to see the fabric were by this fact proven unworthy of their positions. Immediately the king saw the fabulous dress and admired its beauty and texture. The royal family, courtiers, and officers of every grade saw and admired the same. At last, after months of pretended sewing and fitting the garment was completed, and upon an appointed day the swindled monarch paraded the streets in an imaginary dress. Everyone continued to praise and admire the illusion until an unsophisticated fellow exclaimed from the crowd, "The king is stark naked!" And the fool was right.

Are not physicians sometimes caught in the same trap with these courtiers? And for fear of appearing unskilled and unworthy of their profession, simply on the weight of authorities, describe symptoms that they do not see, perceive sounds that they do not hear, and assent to conditions that do not exist.

The art of physical examination depends upon fixed laws. The carpenter percusses the ceiling to find the supporting joists; the musician strains the strings of his instrument to make them in tune, and the surgeon pats the abdomen to diagnose the presence of fluid.

There is no contradiction of physical laws, no guesswork. The same is true of the thorax. Every sound and tremor in the chest is in accordance with natural law. Had we but sufficient knowledge we could never fail to interpret it rightly. Now what produces sound? The vibrations of the air upon the ear. And what produces fremitus? The very same vibrations perceived by the touch. The laws which govern the one govern also the other. Regarding the cause of sound or vibratory motion, the "Encyclopædia Britannica" says, "In acoustics we have to do with the motion of particles forming a connected system. These forces are in equilibrium with each other when the particles occupy certain relative positions. If any new or disturbing force act for a short time on any one or more of the particles, so as to cause a mutual approach or mutual recession, on the removal of the disturbing force the disturbed particles will, if the body be elastic, forthwith move toward their respective positions of equilibrium. Hence arises vibratory motion." "When a wave of sound travelling through one medium meets a second medium of different kind, the vibrations of its particles are communicated to the particles of the new, so that a wave is excited in the latter, and is propagated through it with a velocity dependent upon the density and elasticity of the second medium." "It appears to be well established that while vibrations of a solid are, in general, most readily communicated to other solids in contact with it, they are not so to liquids, and still less so to air and other aëriform fluids." "Likewise a musical string sounds very poorly unless connected with a resonant cavity, or wooden chest, to the wood of which it first imparts its vibratory motion, which then produces stationary waves in the continued air." Dr. Leaming says, "The violin, the most perfect of human instruments, is formed on the model of the human chest. It has two sounding-boards, one at the back and one at the front, and it has sides and ribs." "The vibrations of the vocal chords, or the strings of the violin, are reproduced and multiplied indefinitely in the sound-chamber of the human chest or violin." "Place a non-vibrating body upon the violin, or pour sand or shot or water into it, and its power of reproducing and multiplying sound will be notably impaired, and the same is true of the human chest."

Now, as I have observed, the cause of vocal resonance and vocal fremitus is one. The vibrations of the chest give to the one its character, to the other its thrill. Fill the chest cavity with sand, shot or water, as Dr. Leaming says of the violin, and see if its vibratory movements are not impaired. We know it is true of water, as is the case in pleuritic effusion, in which condition, the authorities tell us, "there is total lack of vocal fremitus." But in cases of pneumonia in which the lung tissue is filled with blood and serous exudation, so heavy even that it would sink in the very water that would prevent vibrations in effusion, these same authorities tell us that vocal fremitus is usually increased.

Take again the familiar illustration of the violin. Draw the bow and notice the fremitus produced by the touch; fill now that instrument with a moist sponge, a close analogue to healthy lung tissue, and repeat the experiment. The fremitus is still there, but less distinct. Now saturate that sponge with mucilage, which will cause it to lose its residual air, and perhaps to adhere to the walls of the instrument. Make it equal in density, if you can, the solidified lung of pneumonia, draw the bow and tell me is the vocal fremitus diminished or increased.

I am aware that in phthisis the emaciated chest-wall may yield a stronger thrill than is ordinarily communicated through both lung and chest. But the increase is not due to the lung, I believe, but to the lessened thickness of the thorax. The same might be true of pneumonia in the later stages, and from the same cause. I am aware, too, that a tumor, cancerous or fibroid, may communicate a cardiac impulse if situated over the course of a large artery. But I do not think that either could be rightfully compared to the inelastic condition of the hepatized lung.

From the foregoing observations it can be readily seen that the writer does not assent to the generally accepted proposition that a solidified lung is a better communicator of vocal vibrations than is the healthy one. It is against reason, against natural philosophy, and, according to my limited observation, against fact. During the past year I have asked my medical friends to observe especially the fremitus in pneumonia and see if it was increased. Some have corroborated my observation and tell me it is not. I wish every reader of this article would do the same, for I only seek the truth regarding it.

For Excessive Perspiration of the Feet.—Dr. Winogradoff advises an application of a five per cent. solution of chloride of zinc. The feet are first washed in tepid water and then the solution is applied by means of a sponge, the surplus being washed off after a few minutes. It is unnecessary to add that the application should be made only by the physician.

THE TREATMENT OF URETHRAL STRICTURE AND A NEW DIVULSOR FOR RAPID DILATATION.

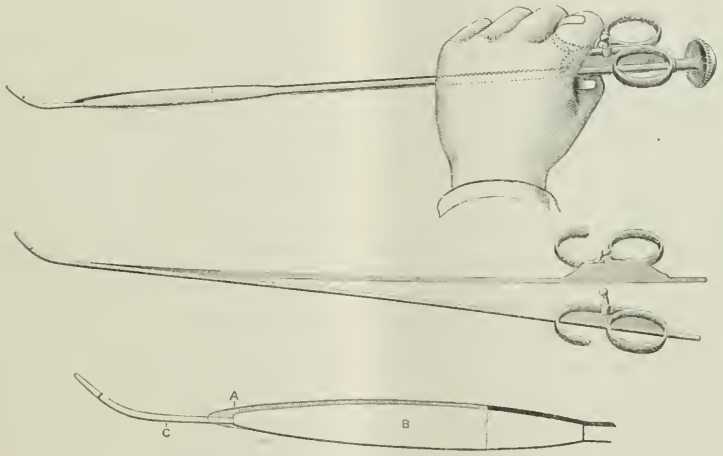
By OTIS K. NEWELL, M.D.,

SURGEON TO THE OUT PATIENT DEPARTMENT OF THE MASSACHUSETTS GENERAL HOSPITAL IN BOSTON.

JUDGING from my personal experience, and reinforcing my opinion with that of many able operators, I am led to believe that the best treatment of urethral stricture is that by the method of gradual dilatation. That in many instances, from the tedious progress made with very small strictures in this way, and from emergency treatment necessitated by retention or other causes, this method cannot be adopted is well known to all.

Gradual Dilatation.—In advocating the method of treatment by gradual dilatation I do not mean to infer that it can always be applied, but I do believe that in cases suitable for it the stricture is brought to the best possible condition in the safest and most comfortable way. It is to my mind a very fallacious argument which applies itself to this subject to demonstrate the curability of stricture. I believe that the true stricture, one which is represented by a greater or lesser amount of organized exudation of plastic lymph, which means just so much scar, or cicatricial tissue, is an incurable condition. Such a stricture may first show evidence of its existence by symptoms which come on according to its manner of origin, traumatic or otherwise, anywhere from a few days to three, five, or thirty years or more after the original cause.

Let me now take what I will call an average case and describe the method which I believe most suited to its treatment. A patient comes to you with a stricture giving rise to troublesome symptoms, such as persistent urethral discharge, slowed stream, over-frequent micturition, or whatever they may be. You examine the urethra with bulbs, as should always be done at first, to determine the number and location of the strictured places, and find two such in the pendulous portion, each about one-half inch in length and 14 French calibre. Forcing this calibre with sounds of next largest size, you find the strictures to be tough, almost cartilaginous, and therefore very resistive to dilatation. This condition, we will say, has been brought about by the gradual organization and contraction of lymph exudation following specific urethral inflammation, in repeated attacks some ten years previous. You now advise your patient as follows: "You have a stricture of the urethra in two places; that practically means that your urethra at those places, from the long-standing inflammation, has gradually become thickened and contracted, just as you may have often seen the scar from a burn. I believe the best way for you to get relieved of this condition is by having the stricture gradually stretched up to the point where you yourself can pass an instrument of sufficient calibre to keep it open. This, however, is only the first step, for in order to keep the urethra in the best possible condition you will have to pass the sound at varying intervals as long as you live. By passing the sound at first each day or two you will, by the pressure and the consequent increase of the circulation in the parts, cause the scar-tissue, or, rather, that portion of it which is not true scar tissue, to become absorbed, and so approach to the nearest possible cure of the condition; but in stricture of the nature of yours the contraction will sooner or later be sure to return unless you occasionally pass your sound." A condition which you have been years in acquiring, you can scarcely expect to make actually vanish in a short time by any method of treatment. You will probably proceed somewhat in this way: at first pass the instrument daily or every other day, according to the toleration of the individual urethra to instrumentation, but with absolute cleanliness and the other precautions, this does not vary much where the strictures are of large calibre; after two or three weeks the sound may be passed every two or three days for a week or two; then, but twice a week for a few months; then once a month for a year or so, and then once or twice a year, merely to determine whether or not the stricture has a tendency to rapidly contract."



A, Central Blade; *B*, Divulsing Staff; *C*, The Guide, Lower End

Of course the rapidity of this process and its regulation are determined by the individual case. Many strictures are easily distended and so readily made to absorb that they seem to all intents and purposes cured; while others are so tough and fibrous that their distention and absorption to the desired degree seem almost out of the question. With this latter class, however, I have seen some surprising results since following the above line of treatment. Notably in two cases where the strictures seemed so tough and fibrous that dilatation even with cocaine seemed almost cruel, so much force did it take. In one of the cases the fibres of the stricture when put upon the stretch with the sound, would snap with a loud report. Both of these cases I dilated, up to 28 French, the patients coming every other day for about two weeks, and then gave directions, after teaching the method of passing the sound, for the instrument to be passed with the same frequency for one month. One of the cases did not return to me for about two months, when to my surprise, I found that a No. 30 French passed without

any difficulty through the urethra. This patient then passed a No. 30 French for a time, at intervals, as above, and then returned for examination. He told me that he felt well in every way, was free from discharge, but there was an uncomfortable sensation at the point of stricture, and that he would like to pass a No. 32 French. I found that that size could be passed, although fitting tightly in the stricture. He has since continued to pass this sound at intervals, and is without symptoms. The other case, the one in which the fibres of the stricture were ruptured with a loud snap, steadily improved, and is now, some two years since the treatment, passing at intervals the sound, a No. 28 French, which I considered sufficiently large for his urethra. In regard to the size of the sounds I believe that for any ordinary case, no matter what calibre the urethra may be stretched to, a No. 28 to No. 30 French sound is sufficiently large, and that if a patient who has had stricture continues to maintain through life a passage into his bladder of this size, he will never be troubled by his stricture, and will moreover guard against any occlusion of the urethral canal, which an unobserved prostatic hypertrophy might bring about.

It is naturally true that this method of procedure has the widest variation, and we must study its application to the simplest case where a stricture established soon after its cause is mostly inflammatory, unorganized, and readily distended, so that perhaps in the most favorable cases complete absorption may be brought about, and cure, if in any case, in such a one made a reality. Of this reality, however, as before mentioned, I am in doubt and believe that where cicatricial tissue has once been established any operation to be curative must be plastic in its nature. The rapidity and frequency of the gradual dilatation must be regulated by the individual case.

Preparatory Divulsion.— Before considering the class of cases where some method of rapid divulsion is necessary, I wish to describe what may be called an intermediary group if they are treated by a method which I have applied to suitable cases with very gratifying results. These cases are those made up of strictures where from very small calibre, almost to impermeability, progress is very slow. I say bougie, as I always use bougies for gradual dilatation where the calibre is below 14 French to avoid the puncturing tendencies of a small stiff metallic instrument. If in these cases, after several days or a week or two, little or no progress has been made, I advise, having in the meantime got the urine and urethra into the best possible condition with internal medication and mild antiseptic injections, the passing of the first size divulsor of my instrument to be below described. I have thus, by means of this preparatory divulsion been enabled to begin with a sound of good size the rest of the treatment, which consists in the gradual dilatation of the stricture to the proper size by sounds according to the method above described. This plan of preparatory divulsion I have at times found very satisfactory, both in private and hospital practice. I have never been troubled by bleeding of any consequence after the passage of the smallest size of the divulsors; nor has this preparatory divulsion been particularly painful, even when done without cocaine, especially in deep stricture. I believe, however, in using cocaine solution, five per cent., for the purpose, of which about one and one-half drachms injected through the urethra with an Ultzmann deep urethral injector is usually sufficient.

Rapid Dilatation.—Finally we will consider that class of cases which from such causes as retention, or inability to afford the time and attention necessary for gradual dilatation, are forced to, what should always be the last resort, divulsion or rapid dilatation. Where this must be done I believe it is best performed by means of a divulsor. With the instrument described below, I believe this operation is made one of absolute precision and scientific correctness. Any rapid operation should be merely the first step in the treatment, which is later to be perpetuated with the proper sized sound passed at the necessary intervals so as to obtain the greatest possible absorption and guard against recontraction.

It may be asked, just what happens when we divulse a stricture? According to my experience, in the examination of a large number of specimens of urethral stricture, we have, as a rule, at the contracted portion of the canal a quite evenly distributed annular deposit of the organized lymph. Now when the divulsor enters this ring or tube, if the stricture be distributed throughout a considerable length of the canal, it breaks its way in lines evenly radiating, in more or less stellate form, from the inner to the outer circumference of the strictured ring. A condition is thus presented much more favorable for the subsequent treatment, than where the band is divided in a single line and direction by a urethrotome.

Against internal urethrotomy I can raise as the chief objections the greater liability to hemorrhage, the uncertainty that the cutting is continued in the same direction, and that even if it were possible to thus divide the intercavernous septum it would be only like dividing the finger-web, which would be sure in time to draw back to its original condition, and unless otherwise treated finally represent that condition with a cicatrix added to it. Most urethrotomes, above all, can only be used in strictures of considerable calibre.

External urethrotomy is, I think by most authorities, regarded as of use and justifiable only in cases of impermeable stricture.

Divulsion of stricture is, I believe, the most certain of the rapid operations and, having the best mortality statistics, the one always to be chosen. One objection to this operation was that in very tight stricture the divulsor coming down might fail to pass through the stricture and carry it through into the bladder, thus invaginating the urethral canal and making a serious laceration. Among many divulsions I have never known this accident to occur, but Dr. William C. B. Fifield, of this city reported to me an account of the autopsy of such a case seen by him in Paris. With my divulsor this accident would be impossible, as will be seen from its construction.

The instrument, as shown in the figures, consists of four principal parts. 1st, the guide *C*, on to which a filiform bougie may be screwed. This guide is made with two steel blades, over which the 2d important part, the divulsing staff, *B*, is carried, and between which the 3d important part, the central blade, *A*, passes. This central blade being between the blades of the guide is necessarily within the stricture when the divulsor reaches it and therefore makes the divulsion of the stricture absolutely certain. The 4th important part of this instrument is the handle, which, as may be seen in the figure, is so arranged that the guide is held firmly fixed in position by the left hand, the ulnar side of which rests against the pubes. Perforation of the bladder wall, a not uncommon accident, is thus surely prevented. Allowing about three inches for the portion of the guide beyond the handle which is taken up by the hand with the instrument held as shown in the figure, there remain about six inches of the guide in the parts beyond. The whole divulsor is twelve inches in length. The instrument should be well depressed, an important point often overlooked in divulsion, so as to have the divulsor pass in the line of the long axis of the prostate. The stricture is thus rapidly, and not indefinitely, divided. Starting with the smallest sized divulsor the tissues give way in their weakest parts, and as the contraction and infiltration at each point of stricture are generally pretty evenly distributed, the lines of rupture are probably located at quite regular intervals in the circumference of the disease. Here, again, by our treatment we have merely brought the urethra rapidly into the condition where the future passage of a sound at the requisite intervals must determine the permanency of the result. Having once passed sounds up to the proper size and taught the patient how to introduce the instrument himself I never advise the use of a bougie for the patient's after treatment. Such an instrument is hard to

clean and not durable. The metallic sound will last indefinitely and can be kept clean. I write for them six inches in length beyond the handle. This is plenty long enough to reach the neck of the bladder and much more convenient to handle.

This instrument is made by Messrs. Codman & Shurtleff, of Boston. It should be cleansed with running hot water and sterilized with steam or 1 to 20 carbolic-acid solution before and after using.

ANTIPYRETICS.[1]

By T. M. JOHNSON, M.D.,

CANTON, O.

THE subject for discussion to-day is a very large one, if we are to take into consideration the many antipyretics which we have at our present command; indeed, if we were to enter into the details of each method by which all such remedies acted physiologically and their therapeutic application, I am afraid our session would be prolonged into many hours, and in the introduction, I will be as brief and concise as the subject will permit.

And then, first of all, what are antipyretics? The common application of the term is a remedy efficacious in curing or reducing fever; and the term fever is applied to a diseased state of the system, marked by increased heat, acceleration of pulse, and a general derangement of the functions.

Many diseases of which fever is the most prominent symptom are denominated fevers, as typhoid, malarial, etc., and during this process of elevated temperature there is more rapid consumption of tissues. And not all tissues are consumed at the same rate; for example, in malaria the blood-corpuscles suffer most, and as a consequence anæmia results; in typhoid fever the nervous system is more profoundly attacked, thus accounting for the many nervous phenomena which you are all familiar with; while in phthisis all parts excepting the nervous system are implicated, thus explaining the preservation of mental activity until death.

And our own chief object in administering the different antipyretics is to preserve the organism from the destructive action of the fever, to ameliorate the action of the poison on the system, and so conduct the case to a successful ending, and to break a paroxysm of fever abruptly which is threatening the life of the patient.

In combating a fever there are two essential questions to be studied, the one is to increase the heat radiation and the other is to diminish its production. The former is only temporary, while the latter is accomplished by the use of well-known antipyretic remedies, to be administered internally as the case demands and to be continued as long as the pyrexia lasts. At the same time we must employ such remedies in addition that will remove the cause of the elevated temperature, for pyrexia is only the expression of the disease and pure antipyretics have no action whatever in aborting the process of a disease, except in the control of the fever.

The first prominent antipyretic that I will call your attention to is water. The use of cold water in fever is no new one, for it was employed in the days of Galen.

Cold water reduces temperature by continuance of its application until the results are obtained. At first in an acute fever, temporarily the heat increases, but as soon as the first shock that is produced or the reflex stimulation is over heat radiation takes place, by the abstraction of the calories from the capillaries. This must be continued for a short period. The best guide is to watch the clinical thermometer, and after a temperature of 105° F. has fallen to 102° F., then it is time to withdraw the cold bath, as there is always a tendency for the temperature to continue to decrease for a while after the cold bath has been withdrawn. The efficacy of this method of abstraction of heat is beautifully illustrated by an experiment of Professor Wood, in which a man was placed in a cold bath, with a temperature of 110° F., with a feeble running pulse of 170, irregular, jerking, slow breathing, and to all appearances near death. The bath was of a temperature of 60° F., and in one minute and a half consciousness was fully restored and in another minute the patient, with a temperature which was comfortable, was trying to get out of the bath. And in cases of high pyrexia with wild delirium, there is nothing which is so effectual, in a short period of time, as the cold bath. And I should say in acute pyrexia, where the life of the patient is in danger from the heat, the latter should be withdrawn as rapidly as possible by means of the cold bath.

In the continued fevers, a primary therapeutic indication is to reduce the temperature. Of course, this should be done if possible by checking the excessive production of heat, but often this is not in our power, and then we are forced to use some other means. During the process of prolonged application of cold the temperature falls, and at this time there is more consumption of tissue. This is explained by the increased amount of carbonic acid gas which is given off at this time, and which rapidly diminishes as the heat is abstracted; and I believe I am not far wrong when I say that those who oppose this method are chiefly those who use the bath in too mild a form, or depend on inexperienced attendants to carry out the directions which perhaps have been given in a meagre manner.

The clinical value of water, as evidenced by tests in various institutions as well as in private practice, has, on the whole, been highly successful, not alone in its antithermic qualities, but in the reduction of mortality, which has been brought from twenty to eighteen per cent. to even as low as two and four per cent. by Brand, of Stettin, in his cases of typhus fever, where the cold bath and the cold pack were the only antipyretics employed, while under the old expectant method which is still in operation to-day, the mortality was as stated, eighteen and twenty per cent.

I am quite positive if the antipyretic treatment of typhoid fever were pushed forward by the use of more cold bathing, cold pack, or the thorough application of the cold sponging, we would quiet more of the nervous phenomena, than by the use of the best of the antipyretic drugs.

The application of this method is very general, and the only exception in which we might display caution would be in severe bronchitic or pneumonic symptoms, occurring in the early stage of typhoid fever, or when this same condition was manifest in the acute exanthemata. A state of collapse due to high temperature might also be considered as a condition in which cold should be withheld.

In the employment of this antipyretic method certain considerations should never be forgotten; it should be borne in mind that we are combating a symptom, and the method should be used only when the symptom threatens injury. The danger-point is considered by eminent writers to be 103° F. in the mouth, unless the pyrexia should be severe. As a general rule, it is very satisfactory to commence with a bath of the temperature of 85° F., and then cool as the case demands. Should the extremities become cool, they can be rubbed so as to maintain circulation, while the body can be bathed with good effect.

In a paper by Professor Winternitz, who is one of the enthusiastic supporters of the cold bath, he says that he is not an advocate of the prolonged baths, or of very low temperatures. He has clearly proven temperature reduction is not the chief aim of this method of treatment, but that the reflex effect upon the nerve-centres, upon the heart, etc., also may be produced by cold packs, ablutions, and half baths in which the water is constantly agitated. And I believe if this latter method is thoroughly applied that the profession will be greatly pleased with the results, and the public be kindly disposed to its application.

One of the many chemical antipyretics which have of recent years come into general favor, is antipyrin, a white

[1] Read at a meeting of the Union Medical Association of Northeastern Ohio, at Akron, O.

crystalline powder of a bitter taste, soluble in six parts of water, and very soluble in alcohol and chloroform. The method of preparation is patented, thus accounting for the high price at which it is sold in comparison with other equally potent antipyretics.

The physiological action as yet is very far from being solved, but this much we all perhaps have observed, that an accumulative action is apparent, and that the drug produces a state of relaxation, and a loss of reflex action. According to Coppola, the drug has no influence on the circulation, and in many cases, after the largest dose, the heart is arrested in systole. Professor Demme says that his experiments showed at first elevation of the blood-pressure, followed by violent tetanic cramps, then progressive falling of blood-pressure, and lessening of reflex; the heart continuing to beat with blood-pressure almost at zero, and death appears to have been produced by failure of respiration, the pupils being constantly dilated. It is freely eliminated by the kidneys, but not as rapidly as it is usually administered, and thus, I have seen a few cases where there were symptoms of accumulative action, in which the patient was distressed with giddiness, pain in the head, and slight nausea.

Antipyrin has been employed with some excellent results in cases of high temperature, but we must be cautious in its continuance; especially is this true if there is much adynamia present. The general opinion is that the collapse seen where it is used exclusively is dependent on its action on the heart, but this is not correct, for the evidence shows that nerve-centres are depressed.

In the fever of pneumonia in the first stage it is an excellent drug to be administered, and it is even more valuable in acute bronchitis; it slows respiration, and has a calmative effect on the nervous system.

The dosage of this drug as set down in our text-books is, I think, entirely too large for safety. Some say a dose of thirty grains to an adult, and repeat until sweating is produced. I should prefer to give a much smaller dose and wait for results after the first dose is given. The effect is usually produced in less time than three hours. By this time we can see the action, and if there is then no perceptible reduction, it is well for us to consider the cause of the pyrexia; if we find that it is of a nervous type we again can give a decided dose and be gratified at the result, but if we find that the fever is due to pus, then quinine is the drug par excellence.

The evidence, as gathered from different authors, shows that the drug has a central action entirely. This is evidenced by the fact that it is partly an antineuralgiac. And its action on pyrexia is on the heat centre, which is located in the medulla, thereby preventing heat production.

Closely allied to antipyrin is acetanilid, which is a drug also derived from the by-products of coal-tar. The drug has much the same action as antipyrin, but while it is a less potent remedy for reduction of high temperature, it is decidedly more of an analgesic, especially so in the migraines. The drug is not so soluble, and is more conveniently dispensed in dry form. The dose is about one-half that of antipyrin, and the time required for the reduction of the fever is about three and a half hours. When there is a typhoid temperature of about 104½° F. a dose of 8 grains is effectual, but in half an hour to an hour the temperature ascends to its original high degree; with this drug, then, there may be a repetition of the dose every four or five hours in order to control the fever. Often copious sweating follows this administration; and in the high temperature of scarlet fever it answers admirably.

The next antipyretic which has come into general favor, and which is now rapidly displacing antipyrin and acetanilid is phenacetine, or acetate of phenol. This is not a true antipyretic, but partakes, like salol, of an antiseptic character. It is a light brown powder, partly soluble in the ordinary menstruums, and should be dispensed in powder or capsule.

Its physiological action is central and peripheral, thus making it a valuable antipyretic remedy in the treatment of typhoid fever, where we get the combined action on the central nervous system, and at the same time its antiseptic action in the intestinal tract. As an efficient antipyretic in high temperature the dosage should be from 8 to 10 grains in the adult, and one dose of that size is more useful than repeated smaller doses. It does not produce any bad symptoms or any depression, although slower in its action than antipyrin or acetanilid, but it is on the whole safer. It is a valuable drug in the fever of influenza, where, in addition to the antipyretic effect, it also acts as an analgesic. It produces copious sweating after a full dose is administered. It is undoubtedly the best antipyretic in the treatment of fever, of the acute exanthemata, and of acute rheumatic fever.

I omitted to state when speaking of antipyrin of the seventeen cases of poisoning which proved to be fatal in one week in Vienna during the prevalence of the influenza. In many cases the drug was bought by the victims themselves in the shops without the prescription of a physician, and in consequence it is now illegal to sell antipyrin without such a prescription.

The new coal-tar derivative, antikamnia, has within the last few months come into general use in some parts of the country. This drug, like phenacetine, is partly antiseptic and strongly analgesic.

My experience has been so limited that I am unable to go into details of its physiological action. Its action as an analgesic appears from the best evidence to be central, and I do not doubt that its antipyretic action is of a central character, thereby depressing heat production.

I ordered 8 grain doses in a case of cephalalgia, to be repeated at the end of three hours until four had been taken, with gratifying results. It causes no excitation and no depression of the vital forces and is best administered in liquid form. It is without disagreeable taste.

A very important antipyretic is salicylic acid. In doses of from 10 to 30 grains it produces an uneasiness of the stomach, and if pushed further gives rise to cinchonism. If given in toxic doses it causes ringing in ears, deafness, strabismus, ptosis, dilated pupil and delirium, the circulation is profoundly affected, and the urine becomes of olive green color due to the cannabin. It is absorbed and circulates as salicylate of soda, and escapes partly changed. After full doses of 10 grains, and repeated, the fever falls and profuse sweating follows. The use of this drug will reduce temperature in large doses in one hour, but is less permanent than the other antipyretics mentioned.

In acute rheumatism it answers a double purpose: first, reducing the temperature; and second, controlling the disease. In full doses it acts as an irritant to the kidneys and stomach. The best and most compatible preparation to be given is in the form of sodium salicylate, which is very soluble, and has a flat, alkaline taste.

Tincture of aconite is prepared from the root and is the best preparation for internal administration. The alkaloids are not a safe and reliable preparation to be dispensed, due to the fact that they are not of a uniform strength.

The symptoms which are induced by small therapeutic doses in man are reduction of force and frequency of the circulation, a sense of muscular quietude and weakness, and a slight tingling in the extremities. If the dose be larger all these symptoms are intensified, and in toxic dose respirations are shallow, marked anæsthesia of the surface is present, the skin is moist with a cold sweat, and the pupils are generally dilated.

From these facts we have only to conclude that aconite paralyzes the peripheral sensory nerve-endings, and that it is also a direct depressant on the centre of respiration. There are only two important indications met by the use of tincture of aconite. The first is to lower arterial tension, and the second is to reduce temperature in sthenic type of fevers not dependent on a deep-seated cause as in the febrile movements of acute muscular rheu-

matism, and the ephemera or irritative fevers of childhood. In the early stages of the exanthemata when no adynamia is present, its influence is beneficial.

Tincture of veratrum viride is a powerful respiratory poison, lessening at first the frequency of the cardiac beat by stimulating the pneumogastrics, but soon losing all control over the heart, owing to the powerful influence which the induced asphyxia exerts.

When taken in small doses it reduces the force without affecting the frequency of the pulse, but after it is continued for some time the number of pulsations are very much reduced.

In full therapeutic doses it lowers the pulse-rate both by a direct action on the heart-muscle, and by stimulating the inhibitory nerves. It produces a general vaso-motor paralysis, more or less complete according to dose. It causes increased diaphoresis, and it is also a strong spinal sedative. It meets two indications, first, to reduce spinal action, and second, to reduce arterial action.

In the early stages of sthenic pneumonia it is of the greatest value in reducing the temperature and in lowering arterial tension, depressing or paralyzing for the time being the vaso motors, and thus allowing an equal distribution of the blood.

In peritonitis, either incipient or developed, it is the drug par excellence.

Under the term of antipyretics I might well include quinine, but as it is employed more as a tonic and curative remedy I have omitted it from the list. Furthermore, its use is so well understood, that a discussion of its antipyretic action might be an infringement on time which may be utilized to a better purpose.

FEBRUARY 10, 1891.

THE RHEUMATOID CONDITION.

BY J. S. PRETTYMAN, JR., M.D.,

MILFORD, DEL.

WE may employ specific terms for characterizing certain definite groups of symptoms for designating morbid conditions of the system, but, after all, disease itself is a unit, every pathological process the result of mal-nutrition, arising from and depending upon an abnormal condition of the blood. With the blood unhealthy the cell-life, the vitality of the body, will necessarily be impaired, and a defective organization that cannot create pure blood will prove a nidus for every lurking germ, where it may develop and multiply, feeding and growing upon the tissues. A robust organization, with all of the bodily functions normally-performed, with perfect nutrition, and with the cell-life properly sustained, will resist and overcome such intrusion.

The strumous subject is an illustration of this. Badly nourished in utero and brought into the world with defective blood-making organs, his vitality continues low, his tissues, as a consequence, are without power of resistance, and when the sickly cells are attacked they readily yield their life, and are devoured by the bacilli tuberculosis. If they were well nourished and made strong by pure blood they would reverse the process and destroy these micro-organisms. It is the "weak," the poorly nourished, whose defective organizations cannot form normal blood, that become the early victims of disease and death.

The similarity of tissue, of organic structure, of parent and offspring, heredity, may account for much of the physical evil, of the weakness, of the degeneration; but aside from this, the startling fact confronts us that more than half of all pain and physical suffering, of all disease, is the result of sensuality—of gluttony, "intemperance," excessive lustful indulgence. The very functions that were instituted to multiply life and prolong existence have thus become, through abnormal gratification and development, instruments of anguish and death—a sad reflection alike upon the intelligence and morality of humanity. If, through a greater advancement, a higher moralization, we can control our appetites, administering to them prudently, wisely not foolishly, rendering them health-giving not life-destroying, we shall have in our possession a latent, inestimable, disease-preventing, healing power. The present sensual desire must be sacrificed for the ultimate good and purpose. If, in the future, physical pain is to be lessened, vitality augmented, life prolonged, it must be through the conservative force of an enlightened conscience, guiding every habit, directing and controlling every desire, rather than by drug administration. We reckon not wisely in trusting to anything else; drugs, after all, can accomplish little; in organic trouble we are almost helpless, and it is the part of wisdom to look to prevention. "Physic is made for fools," and only so long as fools exist will there be occasion for its administration.

Rheumatism, as it is generally regarded, is not properly a disease, it is but a symptom, the expression of a general condition that is manifest in several ways—in lesions of the vascular and hæmatopœtic systems, extending to every tissue and structure of the body. It is characterized by hyperæmia, acute and chronic inflammations, with an overgrowth of connective tissue and a deposition of insoluble salts, arising and resulting from excessive introduction into the economy of normal food products, and through failure of oxidation and elimination of effete material. It is a condition of plethora, the system incapable of burning up the pabulum introduced, while the depurative organs have thrown upon them more than they can accomplish, and thus weakened and paralyzed by excessive stimulation lose their proper strength and function.

It is not necessary to wait for the aching nerve and muscle, the swollen and painful joint, the laboring heart, to protest against the intrusion. The condition earlier than this is manifest in disorders of digestion, in hyperæmia and congestion of the liver, in excessive urate excretions of the kidneys, in acute catarrhs, conjunctivitis, pharyngitis, bronchitis, cystitis, etc., by burning "frosted feet," by purpura and other lesions of the skin, all indicating a morbid product, or products, in the circulating medium, the blood. If the effete material accumulates until joint and heart and viscera are involved, irreparable damage has indeed been done, and the economy will go on lamed and crippled for a time. The diagnosis should be made in the incipiency of the trouble, before the grosser lesions have occurred, and the proper hygienic and medicinal treatment be instituted at once. The urine alone, in the augmentation of uric acid and the urates, gives almost positive evidence of the condition days before other symptoms arise.

In November of 1889, G. R—— came to me with an acute conjunctivitis, both membranes being involved. His breath was foul, his tongue heavily coated, digestion poor, his liver torpid. His skin was dry and harsh, complexion sallow and "muddy," the urine heavily loaded. "brick-dust" deposits falling to the bottom of the receptacle. I suggested as the cause of the inflammation, "full habit," a tendency to rheumatism. Prior to this he had been exempt from the trouble, but in forty eight hours his wrist and ankle became involved, swelling slightly, and disappearing in a few days simultaneously with the conjunctivitis. Three months afterward he experienced a return of the symptoms in identically the same order. In December of last year for the third time he came to me with a conjunctivitis, very slight, saying that he desired treatment for the rheumatism; that it had previously followed the eye inflammation and that he hoped to prevent its reappearance.

I visited Mrs. G—— in the winter of 1888 and found her suffering with a severe laryngitis and bronchitis. Her general symptoms were those of the case above, with the exception of the conjunctivitis and with an addition of purpuric spots upon the skin. I diagnosed "uric acid" as the cause of the trouble, and shortly afterward

several of her joints became involved. In all of her life before she had never felt a rheumatic pain to her knowledge, and consequently she questioned my diagnosis. I was rather glad to have it verified, as it gave her confidence, and the prompt relief that followed under salicylate of soda was gratifying to herself and to me. I have seen her again this month (February, 1891) under like conditions, and the same good results followed treatment.

Mrs. P——, fifty-seven years of age, has been a great sufferer from an excruciating, tearing, burning, tic-douloureux, associated with muscular pain and soreness. She has had this trouble more or less for years, and it generally returns when she considers herself in good health and full habit. She had been treated with belladonna, nux vomica, hyoscyamus, quinine, arsenic, and other like drugs without amelioration of pain, until she was thoroughly discouraged and disgusted. The fact of the pain returning always when she was apparently in the best physical condition, stout and plethoric, associated with a greatly augmented uric-acid excretion, led me to place her upon sodium salicyl. and potassium iodide. The symptoms yielded at once, and it is the only treatment, according to her own admission, that has ever afforded the slightest favorable results. She has not lately experienced a severe recurrence, as she begins treatment, always insisting upon having the medicine by her, at once upon the slightest reappearance of pain.

J. H—— for several years was annoyed with "frosted feet," trying many external remedies in vain. In cold snowy weather the burning and itching always returned, and he could find nothing that seemed even to afford temporary relief. He was subject to catarrhal affections of the throat and eyelids, and the capillaries of his face were dilated and thickened. He also complained of muscular pain and soreness. The rheumatic treatment gave him relief, and for two winters he has had no recurrence.

Most people eat for mere enjoyment to gratify the sense of taste, not to sustain the body, and consequently take more food than is needful. This is especially true in the condition designated rheumatoid, where the emunctories are struggling to eliminate that which has already been introduced, which the system cannot consume and appropriate; the blood thus becoming contaminated. In the treatment of the condition a rigid diet is the first requisite, not only withholding nitrogenous products but to a great extent all foods, so that the economy may burn up and throw out that which is already within. Prolonged fasting is one of the very best measures that can be employed, and it should be insisted upon and enforced; subsisting even for a time upon our own tissues, for if the viscera are preserved there will be no difficulty in the restoration. In an inactive, sedentary life we need but little food, it is indeed astonishing upon how little we may retain bodily heat and vitality. The late exhibition of public fastings should prove wholesome lessons, and while we should never attempt to carry the measure to so great an extent we should yet rigidly discipline our appetites, administering to them all guardedly, temperately, becoming regal masters of every passion and desire.

Large draughts of water should be taken upon an empty stomach to wash out the system—flushing the tubes and carrying out the soluble excreta. It is Nature's cleansing fluid, and its importance may be estimated by the fact that it constitutes ninety per cent. of the entire bodily weight—the basis of all secretion and excretion. Bathing is also an excellent hygio-therapeutic measure, cleansing the skin, stimulating the surface glands and increasing perspiration. The addition of an alkali to the water will neutralize the acidity of the skin and increase its effectiveness. The steam-bath should frequently be employed, it will prove most beneficial.

Vegetable acids should also be taken freely in the form of fruit. By chemical union in the system with alkali bases they produce neutral, freely soluble salts, increasing oxidation and stimulating and aiding the excretory organs in the work of elimination. An orange or an apple before the morning meal is generally acceptable, and will almost always prove beneficial; while fresh or stewed fruits may be taken for dinner. In almost all American households too much meat and too little fruit is consumed. A simple observance even of this kind will tend to increase longevity, and eliminate much pain and suffering.

In our changeable climate, with its varying temperature, its fluctuations in atmospheric moisture, the surface of the body should be well protected, suffused with blood, for otherwise the viscera and internal organs will become congested, and acute and chronic inflammation result. Flannel is an excellent material for the purpose. The wool fibre is a poor conductor of heat, and by this property retards radiation, keeps the heat thrown off from the body closely confined. Silk, probably to a less degree, has also the same property, while cotton and linen rapidly diffuse heat, and consequently fabrics woven from these materials are suitable to be worn only in the warmest summer weather.

If such preventive measures as indicated above should be instituted in infancy and maintained through life the rheumatoid condition would never appear and the occasion for drug administration would not arise. It is surprising how even the youngest infants are overfed, and in most families this "stuffing" process continues through childhood, adolescence, manhood, and old age. With man's heart, and soul, and life thus bent upon fleshly, sensual gratification, in constant violation of Nature's laws, how can we anticipate aught else than pain and suffering? It is nature's protest, a just retribution for such indulgence.

But, while "to err is human," some means must be devised for overcoming physical pain, of remedying the evil, of restoring the injured part or organ, and this is the origin of all medicinal treatment. In the rheumatoid condition it is not surprising that but little is accomplished in this respect, if the diet, if the habits, if the environment of the individual remains unchanged. Brought on by years of excess it cannot be overcome by moments of repentance and good works. Remove all exciting causes, institute hygienic measures, with rigid diet, and then administer therapeutic remedies, and almost invariably improvement will follow and in most cases an entire cure will result. If organic changes have occurred, lesions of the heart, valvular troubles, etc., we cannot hope for a restoration, they will probably remain through life; but if an opportunity is early afforded we may diagnose the condition previous to the occurrence, and with a proper co-operation upon the part of the patient prevent such serious changes.

If the etiology of rheumatism is established as above, then the medicinal remedies indicated are those that increase oxidation and elimination. Upon this supposition the alkalies are administered, and usually with benefit. The salts formed by chemical union with vegetable acids are eliminated as carbonates, increasing the action of the skin and kidneys, and rendering the urine and other excreta alkaline. The action of the salicylates is very similar, and the results are frequently exceedingly gratifying. If the acid itself is administered, it unites with an alkaline base before absorption and is eliminated very much as are the alkalies, decidedly increasing the flow of urine and the secretion of the skin. In acute cases, so far as relieving the pain and swelling of joints are concerned, there is probably no better single remedy than salicylate of sodium. It should be given until its physiological action is clearly manifest, watching its effect upon the heart, and continuing until tinnitus aurium is decided. The dose must be regulated by the susceptibility of the individual.

In subacute and chronic cases the iodide of potassium is an excellent remedy, perhaps yielding better results than any drug in the materia medica. We not only get the effects of the potash, but also the alterative effects of the iodine, and the increase of the nitrogenous break down is

apparent in the accelerated elimination of urea and uric-acid combinations.

There is another class of remedies that have proven in my experience very useful, and I resort to them frequently with confidence; the so called vegetable alteratives and cholagogues—irisin, phytolaccin, podophyllin, leptandrin, etc. They seem to have an affinity for glandular structure, acting upon and stimulating the depurative organs; not only affecting the liver and kidneys, but increasing secretion generally.

If I should be called, then, to what might be regarded as a typical case of acute rheumatism, where the muscles and joints were clearly involved, I should prescribe medicinally somewhat as follows:

℞. Podophil ..... gr. j.
Leptandrin ..... gr. iij.
Sodæ bicarb ..... gr. iv.
M. In pil. iv. ft. S. Two every three hours.

In our climate I should follow this with some preparation of quinine, for it seems generally indicated, and as belladonna would increase peristalsis, and thus aid in expelling the biliary and other excreta formed by the action of the above pills, I would order this combination:

℞. Bellad. ext. ..... gr. j.
Quin. sulph. ..... ʒ j.
M. In pil. viii. ft. S. One every two hours.

Immediately afterward I should give salicylic acid in some form; the following is perhaps as agreeable as any:

℞. Sodii salycyl ..... ʒ iij.
Elix. calisay ..... fl. ʒ iij.
Syr. simp. q. s. ..... ad fl. ℥ iij.
M. S. Teaspoonful every three hours in water.

In most cases I should expect the swelling to subside and much relief to follow. If the case should not, however, progress favorably, if the trouble should assume a subacute or chronic form, I would prescribe:

℞. Potas. iodide ..... ʒ iij.
Syr. stilling. comp. ..... fl. ℥ iv.
M. S. Teaspoonful every four hours in water.

At the same time commencing, alternately every two hours,

℞. Podophyl. ..... gr. v.
Irisin,
Phytolaccin. ..... āā gr. x.
M. In pil. xxx. ft. S. One every four hours.

Occasionally it may be necessary to withdraw the pills for a short time, but a continuous depurative action is desired and must be maintained as far as possible without injury to the patient. With the skin and kidneys excreting freely, with the glandular system and the liver actively at work, and the bowels assisting by free defecation, the economy will quickly rid itself of the poison, and to a great extent will regain its normal strength and health. In connection with strictly hygienic measures I question if a better form of treatment than the above has ever been devised. I certainly have found nothing that gives more favorable results.

Milford, Del., February, 1891.

Another Explanation of the Lessening Population of France.—According to Mme. Lachapelle, a midwife of Paris, the reduced birth-rate in that city is the result of the low standard of education of midwives. A midwife's qualifications are now so slight that many incompetent women have obtained diplomas, and as there is not enough legitimate work to support them they are forced to make money by procuring abortions. But the abortions would not be committed unless the mothers desired them, so that it seems hardly fair to cast all the blame upon the ignorant midwife.

A CASE OF IDIOPATHIC SPINAL HEMORRHAGE.[1]

By THEODORE DILLER, M.D.,
FELLOW OF THE PITTSBURG ACADEMY OF MEDICAL SCIENCE.

Hemorrhage into the spinal cord of traumatic origin has been noted often enough to establish the fact of its occurrence beyond a doubt. But as to whether hemorrhage into or about the cord may take place without an antecedent traumatism some writers are in doubt. However, the majority of authorities do admit that idiopathic spinal apoplexy may occur, but they are all in accord in stating that the condition is found only very rarely.

In view of these facts I trust the case I am about to relate may be of some value as tending to place the existence of the disease beyond the peradventure of a doubt. Although the case is incomplete insomuch that no post-mortem record is included, yet I believe that the clinical history alone will be sufficient to establish the diagnosis beyond doubt.

J. K , a laborer, aged fifty-one, had been in robust health, and was working steadily up to the date of his present illness. He is a tall man of rugged frame; habits of life, good; never had syphilis, rheumatism, nor any prolonged illness. Heart normal.

March 12, 1891.—After performing his ordinary day's work he went to bed at his accustomed time, nine o'clock, feeling as well as usual. But instead of going to sleep in a few minutes as had been his habit, he remained awake, tossing about the bed uneasily until eleven o'clock when he was suddenly seized with an excruciating pain at about the first lumbar vertebræ which radiated from thence around his abdomen and down his thighs. He at once arose from bed in the intensity of his agony, and rapidly walked up and down the room. After a few minutes he sat down upon the edge of the bed and bathed his feet in hot water which his wife had brought for him. While thus engaged he became nauseated, and attempted to vomit several times but did not succeed. The gastric distress lasted only a few minutes. While his feet were yet in the water he noticed that they were becoming numb, and he told his wife about it. Upon attempting to stand erect very soon afterward he was conscious of a diminution of power in his legs. He was greatly alarmed at this discovery and at once got into bed and became aware, a few minutes later, of the entire loss of motion and sensation in both legs. The pain rapidly lessened in intensity, so that he was entirely free from it twenty-five minutes after the initial attack.

The patient feels sure that his consciousness, his memory for words and ability to utter them was never lost or even impaired during the attack. Members of his family bear him out in this statement. They are further in accord in stating that at no time was motion or sensation in any of the muscles above the waist impaired. The loss of voluntary control of the bladder and bowels was noticed the next day and must have occurred coincidently with the pariplegia.

A critical examination the next day revealed the following condition: Paralysis of motion complete in both legs; greatly impaired motion in the abdominal muscles; sensation of all kinds completely lost in both legs—impaired over the lower part of the abdomen. Patient is unable to expel urine or fæces; was not aware that both bladder and bowels required evacuation. No impairment of the mental functions; no pain. Motion and sensation in muscles of upper half of body unimpaired.

Subsequent History.—Pain never returned, save for an occasional twinge. Urine and fæces taken away regularly by mechanical means. The paralysis as described continued unchanged until about April 4th (three weeks after the initial symptoms), when the first signs of the return of muscular power were noted. Patient could, at that time, move toes of left foot. From this time up

[1] Read before the meeting of the American Medical Association at Washington, May 6, 1891.

to the present date (May 1st), there has been steady progress toward recovery. He can now move both legs about the bed, flex knees and thighs. Sensation has largely returned. He is not yet able to expel his urine and fæces, although he experiences the desire.

Remarks.—The very sudden onset of the symptoms would preclude the possibility of the trouble being due to tumor, aneurism, bone disease or myelitis. An embolus would produce sudden symptoms, but it would be highly improbable that trouble of this kind could cause such a complete condition of paraplegia in less than half an hour. So I am forced to conclude that the lesion was a hemorrhage—and a very large one—either in the cord itself, or in the structures immediately surrounding it. I am inclined to think the hemorrhage occurred in the cord itself. As to the part of the cord involved, the symptoms would indicate the lower part of the dorsal region.

The treatment consisted of iodide of potassium, strychnia, and galvanism.

Clinical Department.

INTESTINAL ANASTOMOSIS IN A YOUTHFUL CASE OF FÆCAL FISTULA RESULTING FROM HERNIA.

By C. DREW, M.D.,

JACKSONVILLE, FLA.

James B——, colored boy, aged fourteen, came under my care in November, 1890. He stated that during the previous August he had been ill, and that after a few days of sickness, a fistula appeared and fæcal matter was discharged through it. He gave no history of any severe suffering such as we usually expect from strangulated hernia. Examination showed a fistulous opening directly over the right internal inguinal ring and a second and lower one in the scrotum over the external ring, both discharging fæcal matter, and evidently connected by the inguinal canal. There was an occasional discharge per anum.

He remained under observation, with the hope that nature would accomplish something for him, until January, 1891, but gradually lost flesh and strength; the parts around the fistulæ becoming inflamed and œdematous. He earnestly desired any operation which would offer a promise of relief. January 22, 1891, after an antiseptic bath and covering the fistulæ with antiseptic towels, I brought him under the influence of ether, and made the usual incision at the right margin of the *rectus abdominis* muscle, about four inches long, reaching nearly to the internal ring, and just inside of the upper fistulous opening.

All hemorrhage having been controlled, the peritoneum was opened, and the coils of intestine raised carefully out and covered with towels wet in warm Thiersch's fluid. The invaginated portion of gut was easily found, and proved to be the ileum, about four inches from the ileocæcal junction. As usual, the upper segment was much larger in calibre than the lower. An aseptic silk ligature was placed around both segments as near the ring as it was possible to tie it, and a long narrow forceps clamped around them about one and one-half inch from it. Packing an aseptic laparotomy sponge under the intestine I divided it, raised the intestine from the cavity, and carefully cleaned the stump before removing the sponge. Ligatures of aseptic tape were now placed about four inches from each divided end of intestine. The two ends were now cleaned, invaginated, and the catgut rings applied through slits made in the sides of the gut, as advised by Dr. Robert Abbé in his paper published in the Transactions of the Philadelphia County Medical Society, May 8, 1889.

I found upon reaching this stage of the operation that between the invaginated end of the ileum and the cæcum there was hardly room for the application of the rings.

I intended bringing the stump of intestine through the ring, but at this stage found my patient so exhausted that I could not do so, and allowed it to remain in the cavity with the ligature around it. The cavity was closed with a row of catgut sutures through the peritoneum, and silver wire through the external walls; no drain was inserted. He was put to bed almost pulseless, but rallied slowly under the influence of hot applications and stimulants. Up to the fifth day nothing unusual occurred, and there was no rise of temperature above 99.5°; no vomiting and very little pain or tympanites. He was kept under the influence of opiates, with cracked ice, and an occasional teaspoonful of milk or of beef-tea, but not sufficient to cause intestinal peristalsis. Urine was passed soon after the operation and two good fæcal evacuations were had on the fifth day. From this time the patient gradually sank, and died on the sixth day.

Post mortem examination revealed sloughing of both invaginated ends of the intestine, and partial adhesion of the peritoneal surfaces between the rings. The rings were partly absorbed, and there had been an escape of fæcal matter into the abdominal cavity, with consequent peritonitis and death. In making the exsection of the bowel I had removed the usual **V** shaped portion of the mesentery, and united the edges with catgut sutures, but when the pieces of gut were united side by side, with the ends in opposite directions, there was an unavoidable lapping of a portion of mesentery not removed. It has been suggested that it is not safe to remove even the small portion of mesentery, necessary for the neat invagination of the divided ends of the bowel, for fear of cutting off the blood-supply from the parts, and I suspected that this might have had something to do with the sloughing of the ends. I have felt since doing this operation that Dr. Wyeth's plan of closing the inguinal ring by drawing through it the stump of intestine is the best procedure; if this is not practicable, I think it best to drain the stump well both from within and from without, and leave it in the cavity without any ligature, except such small ones as may be needed to control hemorrhage. I believe it will be always best to insert a drainage-tube.

In the event of the portion of the ileum, between the incarceration and the cæcum, being too short for the application of Dr. Abbé's rings of usual size I think the application of a catgut ring, made after Dr. Abbé's plan, small enough to fit the calibre of the upper segment of intestine, and one of similar size placed within the cæcum, would do better than an effort to place the rings within a limited space.

PILOCARPINE IN PNEUMONIA—A SUGGESTION.

By L. B. TUCKERMAN, M.D.,

CLEVELAND, O.

Up to the present season the internal treatment on which I have chiefly relied in pneumonia has been morphine, tartar emetic, and tincture of aconite ($\frac{1}{60}$ to $\frac{1}{30}$ gr. each of the two former, and ½ to 1 minim of the latter hourly) during the earlier stages, and in the later stages full doses of iodide of potassium—from one to two grains an hour—to promote resolution and support the flagging heart. The latter feature of this treatment was, I believe, first advocated by the late Professor Palmer, of Michigan University. Up to the present season I have been well satisfied with the results of this treatment. This year, however, in the pneumonia following grip, patients have seemed to respond less promptly than formerly to it. Early last winter, Dr. P. H. Sawyer, of this city, related a case to me where favorable results had immediately followed the hypodermatic injection of $\frac{1}{10}$ gr. of muriate of pilocarpine in a congestion of the lungs suddenly supervening in typhoid fever, and which promised to be rapidly fatal. Prompt diaphoresis ensued, breathing became

less labored, in a few hours all signs of the congestion had disappeared, and the patient had an uninterrupted recovery. Profiting by his suggestion, I have been giving pilocarpine regularly for the last four months in connection with the morphine, aconite, and tartar emetic as above mentioned, and find that it softens the cough, allays the dyspnœa, and promotes resolution better than any drug I have heretofore tried. The doses used have been from $\frac{1}{15}$ to $\frac{1}{30}$ of a grain hourly, or in urgent cases $\frac{1}{10}$ to $\frac{1}{4}$ grain hypodermatically in combination with $\frac{1}{60}$ to $\frac{1}{30}$ of a grain of strychnine to guard against too great a depressant action. The good result is probably attributable not only to the prompt relief given to the congested viscera by the dilatation of the arterioles, but also to the fact that pilocarpine powerfully stimulates the excretory functions of the skin and liver, thus tending to free the system from certain toxic products of disease. Without its use I am confident that at least four of my cases which have recovered would have proved fatal. Though early employed, and with good results, in chronic bronchitis with asthma, I am not aware that it has hitherto been used to any extent in acute pneumonia. Of course, the limited number of cases occurring in the practice of a general practitioner, can hardly be claimed to prove anything. The coefficient of error is too large altogether, but the favorable results which have followed its use in pneumonia in the hands of more than one physician in this city certainly warrant a thorough test of its merits by the medical profession at large.

A CASE OF PRIMARY DISLOCATION AT THE ANKLE.

By J. L. BABCOCK, M.D.,
ITHACA, N. Y.

On September 22, 1890, C. S——, a mason, was at work at the top of a tower, which at that time was about seventy feet high. The only means of ascent and descent were furnished by a rough elevator, such as is commonly used in building operations. After the load of brick or stone was taken off the platform of this elevator it was usually allowed to come down "by the run." S—— stepped upon this platform on the morning in question, and neglected to give the signal to the engineer below that the "float" was coming down loaded. The engineer in the meantime had thrown off the brake from the drum, around which the cable was wound, so that the man came down the elevator shaft with great speed. Of course the rapidity and force of his descent were very materially checked by the friction of the drum and the two pulley-wheels over which the cable passed, but he received a violent shock when the elevator struck the ground at the foot of the tower. The man was standing on the little platform with the right foot in advance of the left, in which position the former foot would be in plantar flexion.

The sudden checking of his fall gave his body a strong downward impulse, and thus were presented the conditions necessary for the production of a rare injury. The result of this sudden downward pressure brought to bear upon the foot in plantar flexion was the forcing forward and downward of the tibia and fibula without fracture, thus forming an uncomplicated or primary dislocation at the ankle. Dislocations complicating Pott's or other fractures in this region are very common, but the uncomplicated form of the injury is very unusual.

Dr. Moore, in the article on "Dislocations," in the "Reference Handbook," says: "This form of luxation is an exceedingly rare one, and the different cases often vary much in degree."

Professor Stimson, in his "Treatise on Dislocations" (p. 510), says: "Examples of pure primary dislocations are rare. Malgaigne could find only eighteen reported cases."

The man's foot presented a very striking appearance. It was firmly held in extreme plantar flexion, and was apparently much elongated backward. The ends of the tibia and fibula formed a distinct rounded protuberance, over which the skin was very tightly drawn, immediately over the tarso metatarsal articulations. The two bones had been displaced forward entirely beyond the astragalus.

The injured man was a very muscular fellow, and the spasm was so great that no reduction could be effected until he was anæsthetized, when the foot was very easily replaced. The ankle was tightly packed in a fracture-box for a day or two, and then in a plaster-of-Paris splint. The man left town on October 4th. I saw him on October 27th, walking comfortably, without a limp, with the assistance of a light cane. He had discarded his splint about two weeks before that time, and now had full, unrestricted use of the ankle, which, in consideration of the fact that the joint had been completely disorganized about a month before, surprised me and cast some discredit upon the prognosis that I had made at that time.

AN EPIDEMIC OF PNEUMONIA AND THE CALOMEL TREATMENT OF THE DISEASE.

By WILLIAM R. FISHER, M.D.,
HOBOKEN, N. J.

During a recent visit to the Adirondacks I was afforded an opportunity to see some cases with Dr. E. T. Strong, of Elizabethtown, Essex County, N. J., which presented certain interesting features.

The family among whom the cases occurred live in an isolated farm-house upon a mountain side, at least twelve hundred feet above tide water. Their water-supply is carried in wooden pipes from a spring some distance above any human habitation. The cellar and surroundings of the house were carefully investigated and, although not in a strictly sanitary condition, were in no wise more uncleanly than other places of their class. There were no accumulations of filth or decomposing animal or vegetable matter.

Doctor Strong gave me the following history:

On March 5th he was called to see two babies at this house, one aged ten months, and the other seven months; both of whom appeared to be suffering from bronchitis. At the same time several of the adult members of the family were complaining of "colds."

March 6th.—The elder infant was progressing favorably, but the younger presented the symptoms of broncho-pneumonia

March 9th.—By this time out of fourteen inmates of the house nine were more or less sick, either with the usual malaise, furred tongue, fever, and aching of the grippe, as presented in the epidemic of last winter, or with the more severe symptoms of bronchitis or pneumonia, as shown in the cases of the infants.

On the following day (March 11th), a lad of seventeen showed the signs of pneumonia on the right side, with a temperature of 104° F.

On March 13th, a boy aged fifteen was taken ill in the night. When visited in the morning (after having received a quarter of a grain of morphia and twelve grains of acetanilid, by advice of another physician) he had a temperature of 105.2° F., and the usual signs of pneumonia on the left side.

On March 15th, a girl, aged eight, was attacked in the same way, making the fourth case of pneumonia in the same family within ten days. The latter two cases I examined with Dr. Strong; and I also saw the rapid improvement which followed his treatment. It is to this that I desire to call attention.

The cases were all treated by large doses of calomel, repeated every three hours until four, five, or six doses were taken. The baby of seven months received in all four ten-grain powders. The second case (seventeen

years old) received one hundred and twenty grains in six powders. The third and fourth cases (fifteen and eight years of age) each received a hundred grains in five doses.

There was no hypercatharsis nor undue depression in any case, but relief followed immediately in every instance upon the use of the remedy, and the improvement continued without relapse up to complete recovery.

To those who are inclined to be sceptical, it may seem sufficient to say that these cases took place in young and vigorous subjects who might be expected to recover from pneumonia, even after such an old fashioned heroic treatment.

I would refer such to a communication which Dr. Strong sent to the MEDICAL RECORD in 1889 (p. 291, March 16th), and would also state that he has now treated some forty cases of various ages by this method, with results which have been far more satisfactory to him than those which he was accustomed to obtain by the plan of treatment which is in general use.

KOCH'S LYMPH IN FLORIDA.

By HORACE CAMTHEY, M.D.,

TARRYTOWN, N. Y.

THAT climate has much to do in the treatment of tuberculosis with Koch's lymph, all must admit who are interested in the success of the wonderful discovery, and who have kept posted with the history of its use in different parts of this country. While reading the reports in the RECORD of those who have been testing its value, I witnessed day after day the improvement of a number of patients in Alicea Hospital, located at St. Augustine, Fla.

Early last fall, when the rush began toward Berlin, Dr. F. F. Smith, of St. Augustine, joined the caravan, repaired to Berlin, met Dr. Koch and several of his assistants, studied their methods, and treated a number of patients, spending six weeks or more in perfecting himself in all the minute details in the use of the lymph. On his return, in January, 1891, he at once began the treatment in the hospital built by Mr. H. M. Flagler, and now under the management of a committee of ladies to whom Mr. Flagler presented it.

The first case receiving treatment was from Georgia. When admitted the patient was emaciated to a very low degree; cough so bad that neither could he sleep nor his companions about him; night-sweats — in short all the signs of consumption. Examination of his sputa which were profuse, revealed, under the microscope, the bacilli in great numbers. No cavity could be detected.

From the first this man began to improve. Cough diminished, the sweats ceased, and the bacilli daily grew less, and in two months the man gained eighteen pounds, said he felt as well as he ever did, and was preparing to return to his home.

The second case was no less successful in all points.

The third was one so far gone, that all who examined him pronounced his condition unfit for the lymph. There were one or more cavities in the lungs, and the sputum was loaded with bacilli. Notwithstanding the unfavorable opinion of the doctors the subject pleaded to be treated, taking the responsibility of failure.

He improved slowly at first, and for a time the treatment seemed an utter failure, but after determined perseverance just a ray of hope appeared, which was carefully nursed until there was decided improvement in all his symptoms, the man gaining ten pounds in weight in little over two months.

Of the fourteen or fifteen patients under treatment, improvement commenced at once. There was but one case of consumption which it seemed that no human skill could reach, but the plucky young man begged to be treated and declared he was improving; but I fear it was a delusion so kindly vouchsafed in this distressing disease.

The most marked case of the efficacy of Koch's remedy was visible from day to day in a case of lupus of the upper lip, which had been entirely eaten away. The subject, a man over fifty, the disease of five years' standing, gave signs of improvement after the severest symptomatic effect of the lymph that I witnessed. Pulse ran up rapidly, with high temperature, and severe fever for several days. The poor fellow thought he was poisoned and gave up all hope.

Having witnessed, from the first of January, the treatment of these various cases, I felt it was due to the distinguished author of the lymph to make this statement, feeling assured that the profession would be glad to know of its success, notwithstanding the adverse reports from many parts of our country.

TWO CASES OF IMAGINARY POISONING.

By BERNARD GORDON, M.D.,

CLINICAL ASSISTANT IN DEPARTMENT OF SURGERY, NEW YORK POST-GRADUATE MEDICAL SCHOOL.

CASE I.—November 30, 1890, I was called to Mrs. S——; she was suffering from acute metritis, which was produced by the unskilful and rough manipulations of an ignorant midwife, who treated her for sterility. Having prescribed quinine for the fever, and having ordered hot vaginal injections with sublimate tablets, and the application of hot linseed poultices to the abdomen, I departed. The next morning I was called there to come immediately, the husband of Mrs. S—— poisoned himself with a tablet. On arriving I was surprised to find Mr. S—— without any symptoms of mercurial poisoning: he looked simply pale and frightened; but on inspecting the tablets, I understood that the druggist gave, instead of sublimate 7-3 gr., some other tablets. I went at once to the druggist, and found out that he dispensed hydronaphthol tablets, 1 grain in each; he was sorry for his mistake, but he blamed the apothecary in the neighborhood, who sold them to him also by mistake, instead of sublimate tablets. We can arrive at the following two conclusions: first, that Mr. S—— had extraordinary luck in escaping death, and second, that the druggists were very careless. I think this is the only useful error a druggist ever made, and therefore worthy of report.

CASE II.—April 27, 1891, I was called in a special hurry to Mr. H——; his wife, I was told, poisoned herself. Arriving there I found Mrs. H—— fainting, being supported by her husband and servant. I examined at once her pulse and found it normal. I applied then a few drops of strong aqua ammoniæ on a handkerchief to her nose, and she opened her eyes, began to breathe deeply, and all at once became red in the face and started vomiting. I inquired what poison she took, but nobody except herself knew, and she did not answer. The husband meanwhile explained to me that his wife quarrelled with him at the dinner-table, and when he went away to his store she took some poison; he just arrived before me and gave her plenty of warm water to produce vomiting. "What poison did you take?" I inquired again of Mrs H——, when she stopped vomiting after she had swallowed a few pieces of ice. "A teaspoonful of sulphur!" she answered. I asked her how she came upon the idea of taking sulphur, and she explained to me, that she decided to poison herself by soaking matches in water and then drinking it, but being aware of the fact that matches are made of sulphur, she rather took sulphur, in order to end her life more quickly and without suffering. Blessed ignorance! If she had known a little more than that, the druggist might just as well have sold her five cents worth of phosphorus, instead of the sulphur.

109 HENRY STREET.

Professor Angerer, of Munich, has been appointed professor of surgery in the university, to succeed Nussbaum.

THE VENOUS HUM.

IT has been the custom to teach that a venous hum heard in the neck is an indication of anæmia. Nearly all systematic writers have taught this, although there have been some notable exceptions, like Dr. Hilton Fagge. Recently Dr. R. Apetz investigated the venous hum in six hundred persons, and came to the conclusion that it was of no value whatever as a symptom of anæmia. Dr. Henry T. Bewley (*British Medical Journal*) has examined 200 persons between the ages of sixteen and twenty-six in order to determine the significance of the murmur. Of these 22 belonged to the anæmic class, 31 were slightly anæmic, and 147 were not anæmic. He found that in the 22 anæmic there were 19 murmurs, = 86.4 per cent.; in the 31 slightly anæmic, 27 murmurs, = 87.1 per cent.; in the 147 not anæmic, 85 murmurs, = 57.9 per cent. Dividing the not anæmics into males and females, there were in 104 not anæmic females, 64 murmurs, = 61.5 per cent.; in 43 not anæmic males, 21 murmurs, = 48.8 per cent., that is, not a very great difference. It was noted in each case whether the murmur was loud or not.

Dr. Bewley met with in all 15 excessively loud or roaring murmurs. In 22 anæmic, 3 loud murmurs, = 13.6 per cent.; in 31 slightly anæmic, 5 loud murmurs, = 16.1 per cent.; in 147 not anæmic, 7 loud murmurs, = 4.8 per cent.

The conclusions are the following: 1. Venous murmurs are more common in anæmia than in other conditions. 2. They are present in about fifty per cent. of not anæmic young persons of both sexes. 3. Hence it follows that their presence in any individual case is not a matter of any diagnostic importance whatever. 4. Even the loudest murmurs are not peculiar to anæmia (though more frequent in that condition), and are therefore of but little, if any, importance. I noticed some of the loudest murmurs in very rosy, full-blooded individuals.

While we are not disposed to question seriously these conclusions, it will be necessary to decide by careful counting of the blood-cells and measurement of the hæmoglobin whether persons are anæmic or not. The rough-and-ready method of determining by the general appearance alone will not satisfy the demands of scientific accuracy.

A NEW MORBID HABIT.

IT is the inhalation of tobacco-smoke. Our readers may not agree that it is new, but in the sense that it has become of late years enormously prevalent and a peril that now first confronts society, it may be so considered. Ten years ago only about four hundred million cigarettes were manufactured in this country yearly; now the number reaches into the billions. The cigarette-habit has extended and affected all ages; even the boys smoke more than ever, despite legislation. It is not, however, the cigarette smoked in the ordinary fashion that does harm; it is the inhalation of the smoke. This introduces quickly and delightfully a narcotic poison into the system, and awakens in the *habitue* a sensation as delightful as that produced by opium. The old cigarette-smoker would not exchange a few deep whiffs of his cheap cigarette for the finest Havana that could be bought with gold. It is an intoxication in which he revels and to which he becomes a slave. He is a "cigarette-fiend." He admits it, and smiles over it for a time.

The seriousness of the cigarette to inhalation lies not alone in the fact that it involves a steady absorption of poison; but in the utter hopelessness of the habit, and the entire inability of the indulger to give it up. Once a cigarette-inhaler, always one. In this respect it resembles with painful similarity the opium-habit, to which it has many points of resemblance. One may stop the use of the pipe, or cigar, or the use of tea, or beer, or whiskey, but the morphine and tobacco-inhalation habits, if well established, are practically incurable. The patient may stop for months, or even a year, but he invariably returns to his love. Such is the experience of the writer, corroborated by the testimony of other physicians.

Tobacco-smoke contains aqueous vapor, carbon soot, nicotine, traces of certain organic acids and of such hydrocarbons as creasote, and of products of the aniline series, such as pyridine. It is the nicotine, however, which probably does the harm.

THE MALE NURSE.

THE *Nightingale* discusses in a recent issue the subject of male nurses, *à propos* of the recent graduation of trained male nurses at the school in this city. The *Nightingale* speaks kindly of the male nurse, a fact which would indicate a charity broader than its experience, were it not that its observations bore mainly on the male nurse of the future. Certainly, the average male nurse of the past has been an object of wonder and sorrow for gods and men.

He was a man, in the first place, rather hard to find; if found, it was hard to catch him sober, and if sober, still harder to catch him telling the truth. The male private nurse of bygone days, as we trust, was also rather more expensive than a yacht or opera stock, having in this point, however, the single point of usefulness that he made the doctor's bill appear trivial and even contemptible by comparison.

The male nurse did not get employment every day in the year, and when he got a good thing he knew it. After a few golden weeks, his patient being dead, or, by special providence, well and out again, the nurse would "blow

in " his earnings in a manner delightful to himself and the dispensers of things bibulous.

We are not denying that there were good male nurses in these same olden days, but metropolitan experience has taught that, on the whole, the old Sarah Gamp type of female nurse would not make what is popularly known as " a patch " upon the male specimen. We rejoice that better times have come and that the *Nightingale*, as a representative of the evoluted lady nurse, speaks well of them. One complaint only is uttered, and that is to the effect that men are paid $35 to $40 a week, while women, for the same service, get only $20 or $21.

There seems to be some justice in this complaint. But it is very probable that the men will eventually have to reduce their price as their numbers increase and compe tition becomes keener. Most families, at least, will take a female nurse when possible as long as so great a difference exists.

OUR CORONER SYSTEM.

To be a coroner in this town it is not necessary to be a physician, but to be a politician. Of the four coroners at present only one is, we believe, a medical man. Each coroner has a deputy, however, and this deputy must be a physician. It is not necessary to be a good physician in order to be a deputy, although some of our deputies are able men. But it is necessary to be a good Tammany man.

Our coroner system is a vicious one, though it is better than it used to be. There have been many attempts to change it, but it is unhappily fixed by a constitutional provision, and the gentlemen of this city interested in medico-legal matters are so hopelessly divided among themselves that systematic and persistent attempts at reform seem impossible. We live in expectation, however, that some day the New York Medico-Legal Society and the New York Society of Medical Jurisprudence will amalgamate, and then united efforts to promote medico-legal science may be undertaken. One of the first things to happen in this millennial time will be the death of our present antiquated, political coroner system.

PHYSICIANS AND PERCENTAGES ON PRESCRIPTIONS.

In his presidential address, delivered by Dr. W. R. Cluness, of Sacramento, before the California State Medical Society, in April last, the result of a very laborious investigation into the subject of percentages on prescriptions is dealt with. Dr. Cluness has made numerous inquiries regarding this practice all over the country, and finds it extraordinarily prevalent. Among 106 large towns and cities, the practice was known to exist in 67 and suspected in 39.

It seems to be extremely and scandalously prevalent in San Francisco. One physician of that place writes :

" I have been repeatedly approached by them (apothecaries), and commissions ranging from thirty to seventy-five per cent. have been offered ; indeed, many druggists openly maintain that they can afford, and in fact do give physicians all the receipts of the first prescriptions, contenting themselves with what they call ' the repeats.' . . . In order not to have patients go to another drug store, one druggist has envelopes which are given to the physician, who seals the prescription in the envelope ; another apothecary has prescriptions telephoned to him directly from the doctor's office, and pays for the rental of the telephone. I had one patient tell me that his drug bill was larger than his physician's bill (of course, while under another physician's care)."

There are now two San Francisco druggists who announce a revolt from the system by conspicuous placards, one of which reads : " People's Drug Store ; No Commission Paid to Physicians on Prescriptions ; " and another bears the legend : " No Percentage Drug Store."

We have no doubt that the percentage system exists in this city, though probably not to such an extent as in some other places.

The practice is simply and unqualifiedly a dishonest one, unless the patient is told of it ; and naturally this rarely occurs. But besides being dishonest and degrading, it leads to unnecessary and injurious medication. No physician can systematically avoid the tendency to prescribe medicine freely if he knows it will thereby increase his income. Human nature is too weak and the financial stringency of the physician too strong.

Dr. Cluness has done a service in calling attention to an evil which is evidently wide-spread and serious, and one to which it would be well for medical societies to pay some attention. Doubtless many physicians have fallen into the percentage habit without much thought of the morals of it, or perhaps simply because others do it. A plain presentation of the facts, we believe, will lead every honest man to give up the practice.

AN UNJUST SENTENCE.

For striking a patient suffering from delirium tremens who spat upon him a nurse in this city has just been sentenced to two years and eight months' imprisonment.

We quite agree with sentiments expressed in other journals, that this was a grossly unjust sentence. The nurse was no doubt to blame, but the aggravation was great, and those who are familiar with the character of persons who periodically frequent the alcoholic wards of our large city hospitals will understand that such persons have sometimes to be dealt with sternly. The city policeman who clubs an unfortunate " drunk " into unconsciousness escapes without even a reprimand, but the nurse who does not have a political " pull " is degraded and punished as if he were a felon for a moment's loss of self-control.

The nurse has been punished enough, and ought to be pardoned.

AN IMPORTANT MEDICAL REFORM.

It is reported on good authority that the University Medical College of this city will hereafter abandon in large measure the didactic lecture and teach its students by recitation. Such a change, if made, will be the most important and radical improvement in the system of medical teaching that has been undertaken for many a day. We have long argued in favor of abolishing the didactic lecture, as being an absurd relic of an ancient and effete system of instruction. There has never been any valid defence offered in its favor, except that the recitation

method is more laborious, more expensive, and one which, perhaps, adds less dignity to the professorial chair. Such things, however, are not to be considered in searching for the best method of teaching. It is the student's good which must first be looked after, and it is by the drilling and marking of the recitation that this good is best obtained. We are very glad to note the progressiveness shown by the University Medical School.

FOUR YEARS' MEDICAL COURSES.

The proposed establishment of a four years' graded course at the Harvard Medical School and at the University Medical College of Pennsylvania, marks another important stride in the direction of furnishing thorough medical education in this country. There can be no doubt whatever that four years is none too short a time to acquire medical knowledge and skill sufficient to practise our art in its best manner. In three years one can by diligence master the rudiments; but at least another year is necessary to acquire the technical skill necessary to do routine work in the specialties.

At present Boston and Philadelphia promise soon to be ahead of New York in advanced educational methods. But we trust that this will not long be the case. Columbia College is rich, and the University of the City of New York is likely soon to become so. We trust that these two institutions will not be lagging in the race. Bellevue Hospital Medical College is also alert and resourceful. It will not allow its rivals to pass it in efforts at advancing medical education.

IMMIGRANTS AND DISEASE.

The lunatics and diseased persons sent back to Europe from the State of New York during the last seven years numbered, in all, 1,374. The New York *Times* has compiled an interesting table showing the condition of those "returned with thanks." It is as follows:

	1884.	1885.	1886.	1887.	1888.	1889.	1890.
Total number	114	152	175	216	323	229	165
Lunatics	11	10	19	25	14	10	8
Imbeciles	19	21	24	26	26	6	7
Feeble-minded	34	78	33	52	91	62	33
Vagrant and Diseased	7	13	18	27	87	42	29
Decrepit	8	5	23	10	29	31	19
Cripples	9	9	8	21	13	12	15
Blind	3	2	3	8	4	5	..
Epileptic	2	1	9	7	8	8	5
Paralytic	2	1	..	5	3	3	3
Deaf-mutes	1	..	..	3	..	..	..
Otherwise infirm	18	12	38	32	48	50	46

Medical men have occasion to know that but a small percentage of the diseased and dependent classes are returned to their homes. One-third of our insane are foreign-born, as is also over one half of our dispensary and hospital population.

By far the largest proportion of this useless and expensive increment comes from Germany, Austro-Hungary, and Poland, though Russia and Italy have of late been greatly increasing their quota. Immigration furnishes physicians a rich field for pathological study, but it is unremunerative to the profession and expensive to the community.

THE PRESCRIPTION OF IRON IN ANÆMIA.

There is no drug in the Pharmacopœia which is given more than iron, or in as many forms. The list includes bromides, iodides, sulphates, carbonates, chlorides, phosphates, pomates, citrates, malates, peptonates, albuminates, with many others. The favorite forms are no doubt the carbonate, the chloride, and organic salt, like the citrate. The question sometimes arises whether it, after all, makes any difference.

Another point on which there is great variance is the dose. It is shown by physiologists that the blood of the human body contains only about a drachm of iron altogether, and hence it might be inferred that a grain or so daily ought to supply any deficiency. Yet there is a feeling among many physicians that very large doses ought to be given.

A shock will doubtless be given to the profession by the following letter of Dr. T. Clifford Allbutt (*British Medical Journal*), who attacks that idol of the ferrous therapeutist, the Blaud pill. Dr. Allbutt says: "In his interesting articles on anæmia, Dr. Stephen Mackenzie discusses with some care and anxiety the proportions of alkali to be combined with sulphate of iron in Blaud's pill. Let me assure Dr. Mackenzie and your readers that these proportions are of no importance whatever, and that the alkali may be omitted without therapeutical loss, and with much practical convenience.

"For the last five years of my practice I ceased entirely to use the alkali, and my results were equally good. The mistakes and failures in treating adolescent and chlorotic anæmias are often due to the prevailing economy in the use of the iron. With five or even ten-grain doses of citrate of iron little real progress may be made in many cases. No form of iron is so efficient as the sulphate, of which gr. j. thrice daily is to be given for a week, then two grain doses for ten days, and so on till nine, or even twelve, grains are taken in the day. The drug should be gradually reduced in like manner, and the course should never be less than three months in duration, or relapses may occur. In obstinate cases the addition of one-thirtieth grain of strychnine, or one-quarter grain of phosphide of zinc are invaluable aids. Most patients require the inclusion of one-third to one fourth grain of extract of aloes to prevent the constipating effect of the sulphate, but Dr. Mackenzie rightly denies that constipation is the cause of chlorosis, or even generally coincident with it. This error is due to reasoning from an insufficient number of careful records.

"Iron pills should be carefully made from the dried sulphate, and not with gums, which by hardening make the pills insoluble. In any case it is better to order the pills to be freshly made every week, if not even more frequently. Patients who are unable to take pills are best treated with the saccharated carbonate of iron, of which three or four large teaspoonfuls may be given in the day."

Some Time Ago the Russian Government forbade women to attend medical lectures at the universities. The Government is now, however, preparing to establish a Female Medical Institute, where women can learn medicine by themselves.

News of the Week.

The Hospital Graduates' Club held its sixth anniversary dinner at the "Arena," on the evening of May 28th. Dr. James E. Newcomb, Vice-President of the Club, presided in the absence of the President, Dr. Henry. Speeches were made by Drs. Newcomb, D. B. St. John Roosa, E. L. Keyes, E. M. Culver, Frank P. Foster, D. Bryson Delavan, and T. R. Pooley. The speakers dealt largely with reminiscences of their hospital life, and narrated many amusing anecdotes of the great lights of former days. Some needed reforms in hospital management were touched upon, and especial emphasis was laid upon the necessity of giving to medical men a representation upon the governing boards, so that they might have a voice in the management of the hospitals which they served. The members of the Club, as representative hospital men who knew by experience the evils so often attending lay interference in strictly medical matters, were urged to throw the weight of their influence on the side of this necessary reform. About seventy five of the members of the Club and invited guests sat down to the table, and when they rose it was with the conviction that this had been one of the most successful and in every way enjoyable medical reunions of the year.

For Victims of Opium, Chloral, and Cocaine.—Brooklyn is soon to have a home for victims of the opium, chloral, and cocaine habit. A site for the proposed new institution has been secured in Brooklyn Avenue, Park and Prospect Places, and the plans for the building have been approved. The building will cost about $100,000, and will be completed before the close of the year. One-quarter of the capacity of the home will be reserved for poor patients, and an endowment fund of $60,000 is at present being raised to provide for their care. The institution will be under the immediate charge of Dr. J. B. Mattison. The Board of Directors includes the Rev. Dr. Charles C. Hall, the Rev. Dr. R. R. Meredeth, Dr. J. O. Wilson, Dr. A. J. C. Skene, the Rev. Dr. Charles H. Hall, Dr. John C. Shaw, Gen. C. F. Christensen, Dr. Allan McLane Hamilton, and Dr. George F. Shrady.

A Case of Heteradelphia.—Professor Virchow showed before the Medical Society an adult Indian who bore upon his breast a complete twin. The malformation was of the kind when one child does not arrive at full development and had a sort of parasitic relationship to the other, it was dependent on it as regarded circulation. It represented one of the forms of acardiacia, for there was no doubt that no heart was present in the second child, there was therefore only a single motor cardiac force. In the collection in the Pathological Institute there was a similar preparation which represented a perfect reproduction of the one shown. That preparation was subjected to the most careful anatomical examination by Rudolphi, and was skilfully sewn together again. It was particularly shown that the whole of the parts were dependent on an arterial connection which sprang from the left sub-clavicular. It was readily seen that with such relations the circulation could not be very favorable, and when such a parasite was exposed to the air for a long time it cooled very quickly; the hands and feet became stiff and the circulation fell. It was remarkable that in all these cases of heteradelphia the head of the parasite was absent, also the vertebral column with the spinal cord, the nervous system generally, and that only the external parts were present. The whole sensitive innervation of the parasite was dependent on the main body, and that was one of the most remarkable things with this heteradelphia, by which it differed strikingly from other forms of duplicity. The parasite had no anus, but it had a pair of nates with a furrow between them, but it was imperforate. There was also a penis, regularly perforated, that from time to time passed urine, but there were two urinary apparatus there. Sensibility at this spot was dull, the man said he could not feel distinctly when urine came out of the penis.—*Medical Press.*

Resignation of Dr. Francis Minot.—Dr. Francis Minot has resigned the Hersey Professorship of the Theory and Practice of Medicine at the Harvard Medical School.

Four Years' Course at the Harvard Medical School.—The faculty of the Harvard Medical School, at their last meeting, voted that with the class entering in September, 1892, the regular course necessary to obtain the degree of M.D. shall be four years.

A New Medical Governor.—M. Lanessan, the recently appointed Governor-General of Tonkin, is, like many more of the public men of France, a member of the medical profession. He was member of parliament for one of the constituencies of Paris in the present Chamber of Deputies, resigning this distinction on his new appointment. He was formerly a surgeon in the French Navy, and a diligent student of natural science, in which section he was a past Assistant Professor in the Paris Faculty of Medicine.

An Obstetrician's Liberality.—Professor Tarnier, the celebrated French obstetrician, has given a practical expression to his grief at the diminishing natality of his race, and has promised one hundred francs to every family at Arc sur-Fille, the village which had the honor of giving him birth, which shall have contributed an infant to the population of France during the year 1892. This is a novel way of inducing married people to fulfil their *rôle* in nature, but they cannot complain of not having had sufficient notice.

The Journal of Gynecology.—A monthly journal of gynecology, obstetrics, and abdominal surgery has just appeared, edited by Dr. Charles N. Smith, Toledo, O.

Dr. E. P. Bailey died at Marlborough, Ulster County, N. Y., on May 24th, of Bright's disease, aged seventy-three.

The Oldest Surgeon in the world is Mr. William Salmon, of Prullyne Court, Cowbridge, Glamorganshire, who has just attained his one hundred and first birthday. Mr. Salmon is a member of the Royal College of Surgeons. He was born March 16, 1790.

An Italian Pharmacopœia is about to be published. This will be the first national formulary, those hitherto in use having been of the most varied description, consisting largely of more or less correct translations of French formularies, and having no general or official recognition.

Hospital in Natick, Mass.—A will which leaves the town of Natick $150,000 for a hospital has been sustained in the lower court, but will be appealed to the Supreme Court.

Crystallized Chloroform.—The Swiss physicist, Raoul Pictet, has discovered a method of preparing crystallized chloroform for commercial use. Kept in this form it cannot undergo any changes or contain any impurities.

Professor Tyndall on His Thrombosis and Dr. Holmes on His Failing Senses.—Professor Tyndall writes to *The Times:* "Gout is a 'demon multifaced,' and it may be that I am suffering from gout. But the accurate description of the matter is this: The pulse of the right foot beats normally, which indicates a free passage through the arteries, but the right limb is swollen throughout, indicating that its deeper veins are blocked in a manner well known to physicians. With regard to the restoration of the return current, all is uncertain, but under the most favorable circumstances it will require six weeks of absolute quiet to restore the normal condition of things." Dr. Holmes, in declining an invitation to a Unitarian festival, writes: "My senses, if not my wit, have paid their tribute to time. I am not, it is true, the blind mendicant for whom, according to the veracious penny-a-liner, our good Dr. Peabody took me when he threw the quarter of a dollar into my hat. But they that look out at the windows begin to feel as if the windows wanted washing, to say the least. I could not see all the bright faces quite so clearly as I could before the big units had climbed up the back of my decades. I could not hear the lively sayings quite so well as I could before my locks went unanimously for unlimited silver coinage. So you must allow me to wait and read in the morning papers of all that you say and do, and in the meantime accept my cordial wishes for the success and enjoyment of the meeting and the welfare and long-continued prosperity of the association. Believe me, yours very truly, Oliver Wendell Holmes."

The Journal of the American Medical Association.—At a meeting of the trustees, May 13th, Dr. G. C. Culbertson, editor of the *Cincinnati Lancet and Clinic* was appointed editor of the *Journal.*

Medicine and Theology.—The *Journal of the American Medical Association* quotes the comment of a noted college president, that medical men are becoming more skeptical and dangerous to the growth of ethical truth. In reality, says the *Journal*, this is the exact opposite of the facts. Statistics will show that more physicians are both active and passive church members than ever before. In every town and city in the country medical men will be found actively supporting almost every Christian and philanthropic movement for the elevation of the people. The real students of all the writings of Darwin, Huxley, Spencer, and others, will never be skeptics or obstructionists to ethical truth. The half-learned are the only dangerous men.

Epidemic of Typhoid.—Carroll County, O., is overwhelmed with a severe type of typhoid fever. Physicians from neighboring counties were called on for assistance, the local doctors being unable to care for all the cases properly.

To be Tried Under the Code.—A San Francisco physician, member of the San Francisco County Medical Society, read a paper before that body, and the following day extensive abstracts of his contribution appeared in the daily public press, presumably with his knowledge, consent, and assistance. Charges were promptly brought against him for a violation of the Code of Ethics, and his trial was set for an early date.

Diuretin is the name of the latest German synthetic preparation brought before the therapeutic world. It is a natro-salicylate of theobromine, and, as its name would indicate, is recommended as a powerful diuretic.

The Maine Medical Association.—The thirty-ninth annual meeting of this Society will be held at Portland, Me., Tuesday, Wednesday, and Thursday, June 9, 10, and 11, 1891. Attention is called to the rule of the Association, that papers which exceed twenty minutes in the reading, must be presented either in abstract or by extracts. Members who desire to offer voluntary papers or reports of cases are requested to communicate by letter or in person with Dr. F. E. Small, 359 Congress Street, or Dr. W. L. Dana, 660 Congress Street, Business Committee.

Dr. William S. Thompson, one of the oldest and most successful physicians of Maryland, died at his home, "Weymouth," about one mile north of Warren, Md., on the afternoon of May 14th, aged seventy-six years. He had been in failing health for several years, but it was only within a comparatively short time that he had relinquished active practice. Dr. Thompson was a native of Paterson, N. J. He graduated with high honors at the University of the State of New York in 1836, and located at Warren, Baltimore County, in 1844. Here he was in continuous practice up to within a very short time of his death, his entire professional life rounding out four years more than half a century. He was a strong Union man during the late war, and afterward a Republican, although he never took an active part in politics. He leaves a wife and four children—three sons and one daughter.

Dr. Joseph P. Logan, editor of the Atlanta *Medical and Surgical Journal*, died at Atlanta on June 2d. He was born in Botetourt County, Va., on November 9, 1821. Dr. Logan was a member of the Atlanta Academy of Medicine, of the Georgia Medical Association, and of the American Medical Association, and of the State Board of Health of Georgia.

St. Luke's Hospital and the House of Rest for Consumptives Consolidated.—The consolidation of St. Luke's Hospital and the House of Rest for Consumptives, at Tremont, went into effect on June 1st. The plan was ratified by the trustees of the two institutions two months ago, with the understanding that the hospital should maintain at least forty beds for the care of consumptive patients. There will be no material change in the staff or management of either institution.

Dr. S. Stocking died at his home in East Glastonbury, Conn., on Sunday, May 31st. During the war Dr. Stocking was surgeon of the Eighth Connecticut Volunteers, and was seriously wounded in one of the engagements.

The British Nurses' Association will hereafter bear the title of Royal, in obedience to a command of Her Majesty Queen Victoria.

Obituary.

FORDYCE BARKER, M.D., LL.D.,

NEW YORK.

Dr. Fordyce Barker died on Saturday, May 30th, of an apoplectic stroke. The seizure occurred on Thursday, and he remained partially conscious until Saturday morning.

He was born at Wilton, Me., May 2, 1818. He was graduated from Bowdoin College in 1837, and went to Boston, where he studied medicine with Dr. Henry I. Bowditch and with Dr Charles H. Stedman at the Chelsea Hospital. Afterward he studied in Edinburgh and Paris, and received the degree of M.D. in the latter city in 1861. In this country he began the practice of his profession at Norwich, Conn., in the following year. He made a specialty of obstetrics and women's diseases, and in 1845, when but twenty-seven years of age, he became Professor of Midwifery at the Bowdoin College Medical School. In 1850 he was elected to a similar post in the New York Medical College, and came to this city, where he had since lived. In 1852 he became attached to the staff of Bellevue Hospital, where he remained until 1874. In 1860 he also filled the position of Professor of Clinical Midwifery and Diseases of Women in Bellevue Hospital Medical College. In addition to the large private and consulting practice which Dr. Barker had, he was consulting physician to Bellevue, the Maternity, the Cancer, the Woman's, St. Elizabeth's, and the Children's Hospital.

Dr. Barker was a prominent member of many medical associations, chief among them being the New York Academy of Medicine, of which he was president from 1878 to 1884; the New York County Medical Society, the New York Obstetrical Society, the New York Pathological Society, the Medical Society of the State of New York, of which he was formerly president; the New York Medical and Surgical Society, and the American Gynecological Society, of which he was the first president, in 1876. He was also Honorary Fellow of the Royal Medical Society of Athens, and a member of the Obstetrical Societies of Edinburgh, London, Philadelphia, and Louisville, and of the Philadelphia College of Physicians. In his private practice, also, Dr. Barker was very widely known. He attended General Grant in his last illness, and was the family physician of many of the leading families in this city. Outside of his professional position, however, which was high, Dr. Barker was most popular as a man, and was universally regarded as a thoroughly lovable, refined, and noble character. He had cultivated musical tastes, and was a student and lover of literature. It was at his house that Dickens was a guest when he visited this country. Thackeray was also an acquaintance of Dr. Barker's.

To medical literature he contributed many valuable works in the way of papers, lectures, and articles published in medical magazines. He was the author of a work on the "Puerperal Diseases," of which several editions have appeared. This work was translated into Italian, and was published at Milan in 1875, and afterward made its appearance in French and German. He also published a work on "Seasickness," which has been widely known.

Several colleges have conferred honorary degrees on Dr. Barker. Bowdoin College, Edinburgh University, and Columbia College had all given him the degree of Doctor of Laws.

In personal appearance he was a remarkably fine-looking man, of tall and commanding figure. Since an attack of typhoid fever which he suffered abroad about five years ago, however, he had failed considerably. He was the son of a physician, Dr. John Barker. He married in 1844 Miss Elizabeth Le Dwight, who survives him. He leaves also one son, Fordyce D. Barker.

The death of Dr. Fordyce Barker removes from our midst one of the most honored and beloved of men. As an educated and cultured gentleman, he was a type we all delighted to respect and emulate. It is difficult to keep within the bounds of sober estimation of the good qualities which made up his well-rounded character, and still do justice to his merits as a friend, counsellor, and brother. His long and successful professional career was so free from spot or blemish that it can well serve as a model for careful imitation. From it may be learned the much needed lesson that the highest aims of human endeavor are best and most effectually realized in the good we can do to others. Dr. Barker was pre-eminently a man who served such a purpose, and the fact needs only be mentioned to be endorsed by everyone who knew him. The rare and estimable qualifications which fitted him for his wide sphere as a leader, not only in his profession, but with the public at large, are too well known to need reference. And while with sorrow we record the end of a life of singular usefulness, we are happy in the thought that it was spared to us up to the full allotment of three score years and ten.

Resolutions of the New York Obstetrical Society.—*Resolved*, That by the death of Dr. Barker the Obstetrical Society has sustained the loss of its oldest and most eminent Honorary Fellow, who, though prevented in recent years, by reason of his failing health, from taking an active part in its scientific work, always maintained a lively interest in its proceedings, and rejoiced in its prosperity.

Resolved, That the Fellows of this Society, recalling his numerous acts of kindness toward them individually, feel that when his great, warm heart ceased to beat they lost not only one who was the finest type of professional honor and dignity, but a long-tried personal friend.

Resolved, That they will cherish his memory as that of a wise physician and a chivalrous, high-toned gentleman, whose name will ever remain a synonym for all that is noblest and best in our profession.

Resolved, That we respectfully tender to the family of the deceased our sincere sympathy, and that copies of these resolutions be sent to them and published in the various medical journals. For the Society,

Thomas Addis Emmet, M.D.
William M. Polk, M.D.
Joseph E. Janvrin, M.D.
Henry C. Coe, M.D.

Resolutions of the Medical Board of the New York Maternity Hospital.—*Resolved*, That by the death of Dr. Fordyce Barker, Consulting Surgeon to the Hospital, we have met with the loss of a warm personal friend, as well as of a valued counsellor. Although unable, by reason of increasing infirmities, to take an active part in the work of the Hospital, his interest in its welfare, and in the branch of medicine in which he was so eminent, never abated. In common with the whole profession, we cherish his memory as that of a wise physician and a good man, who died full of years and honors.

By the Board,
Henry C. Coe, M.D., *Secretary*.

In Honor of the late Dr. Fordyce Barker, the Commissioners of Charities and Correction ordered that the entrance to Bellevue Hospital be draped for thirty days, and the flags be at half-mast. A memorial tablet was also authorized to be placed in the Hospital.

The Funeral Services of the late Dr. Fordyce Barker were held on June 2d, at St. Thomas's Church, and were very largely attended. The Fellows of the Academy of Medicine, and the members of the County Medical Society met at the Academy and marched in a body to the church. A delegation of students from Bellevue Hospital Medical College was also present. The pall bearers were Charles B. Hoffman, Clarence A. Seward, Frank V. Bond, D. H. Babcock, General George W. Cullum, W. H. Porter, Walter Langdon, and Judge Abraham R. Lawrence. The services were conducted by Bishop Potter, the Rev. Dr. Dix, and the Rev. Dr. Brown.

Society Reports.

American Medical Association.

FORTY-SECOND ANNUAL MEETING.

Held in Washington, D. C., Tuesday, Wednesday, Thursday, and Friday, May 5, 6, 7, and 8, 1891

(Continued from page 609.)

SECTION ON DISEASES OF CHILDREN.

THIRD DAY, THURSDAY, MAY 7TH.

No session of the section was held on Wednesday.

Necrosis of the Maxillæ, with a Report of Three Cases.—DR. W. B. JOHNSON, of Paterson, N. J., presented the paper. In this condition the inferior maxillæ is the affected part in sixty-five per cent. of the cases. The causes are periostitis, periodontitis, ostitis, and osteo dentitis, irritation, dentition poisons, exanthemata, traumatism, etc. There are four pathological stages—hyperæmia, hypertrophy, suppuration, and new formation. The treatment is to be applied with reference to the existing condition, and consists of active antiphlogistic measures, both local and general. Incision, if indicated, should be made early, and followed by the most perfect irrigation. The most rigid antisepsis with the removal of any dead bone as soon as detachable are essentials. And lastly, vigorous tonic and stimulating treatment should follow. The prognosis is good. The jaw movements generally remain perfect enough for all practical purposes. If new bone does not form the gap is filled in by hard fibrous tissue. We may necessarily remove some of the permanent teeth while in process of formation, and even if the latter do come in with good root structure, they decay later.

The Prophylaxis and Treatment of Diphtheria.—DR. J. LEWIS SMITH, of New York, read a paper on this subject. The room should be disinfected by adding to one quart of simmering water one to two fluid ounces of the following mixture:

℞. Oil of Eucalyptus..... ℥ j.
Carbolic acid..... ℥ j.
Turpentine q.s. ad..... ℥ vj. to ℥ viij.

Everything and every person not absolutely necessary for the comfort and management of the patient should be excluded from the sick room. Physicians undoubtedly conveyed the disease. They should always examine the fauces by standing behind or at the side of the patient so that no ejected mucus may come upon them. After each visit they should wash thoroughly, in a sublimate solution, hands, face, and beard. Walking cases without fever, anorexia, or malaise diffused the disease. Daily inspection of the fauces of school children had been proposed. Convalescents should not mingle with healthy children for four weeks. He admitted the full claim of the Klebs Loeffler bacillus to be the cause of the disease. It was a surface microbe—never penetrating the interior of the body, but attacking only mucous surfaces or cutaneous abrasions. It produces a ptomaine containing carbon, hydrogen, azote, sulphur, and oxygen, which by absorption through both blood and lymph channels causes the nephritis-granulo-fatty degeneration of heart muscle and paralysis.

The treatment should embrace hygiene, diet, and alcohol. Rectal alimentation could be followed for a time. Failure of appetite rendered the outcome doubtful. Diet could embrace milk with sarco-peptones, beef tea, or meat juice, and the various predigested compounds. Large and frequent doses of alcohol were positively necessary. It is quickly eliminated and often will save life unless blood-poisoning has actually set in. In the proportion of one to five it has been shown to have a destructive action on the growth of the bacillus.

Locally we should remember that normal epithelium was a barrier to the germ's entrance, and hence our remedies should be such as not to destroy the epithelial covering. Denuded or diseased surfaces were favorable starting-points for the disease. Corrosive sublimate, 1 to 8000; carbolic acid, 1 to 50; salicylic acid, 1 to 80, had proven of service in arresting the germ growth. Potassic chlorate was useless in this direction, and he had come to discard its internal employment entirely. It had undoubtedly caused nephritis in many cases. The corrosive sublimate could be given by nasal injection, gargling, and internally. Where the false membrane was very thick and tenacious equal parts of tincture of iron and glycerine should be given three or four times a day. Loeffler himself uses a mixture of carbolic acid, alcohol, and distilled water for the mouth. Our local remedies should be penetrating. Therefore glycerine and water, never syrups and mucilages, should be our vehicles for all local applications. The officinal solution of iron chloride might be diluted three or four times for this purpose. While it undoubtedly contracted the vessels it was often painful. It congeals the muco-pus of the fauces. Carbolic acid, Monsel's solution, and glycerine could be advantageously used in this way. For nasal disinfection a saturated solution of boric acid was preferable.

For internal treatment, iron assisted the anæmic condition. Vegetable tonics, including quinine, were probably useless, as were also quinine insufflations in the oral cavity. The main reliance was to be placed on the bichloride. He was in the habit of giving a two-year-old child $\frac{1}{12}$ grain every two hours; four years, $\frac{1}{10}$ grain; six years, $\frac{1}{8}$ grain; ten years, $\frac{1}{4}$ grain. His solution was made by dissolving the sublimate in alcohol and adding elixir of bismuth and pepsin. Sublimate solution, two grains to the pint, could be used for the nose. The mercurial should be continued at least one week, unless diarrhœa supervened, but not longer. Calomel had been suggested. Many gave an initial dose, and some continued it through the entire disease. It undoubtedly increased the anæmia. Of late it had been given in the New York Foundling Asylum by sublimation, from ten to forty grains being used, under a tent made over the patient's bed. The indication for its use was the supervention of hoarseness. The attendants had been salivated in several instances, but the patients were apparently not injured. It seemed to lessen the necessity for intubation. The process might be repeated in three or four hours. The percentage of recoveries from intubation where necessary was better in the calomel cases than in others. For the nephritis he gave iron, and for the paralysis tonics, strychnine, and electricity.

DR. A. SEIBERT, of New York, remarked that we must see way down to the epiglottis in order to have our examination amount to anything. Children should not be allowed to kiss each other when there was any sore throat about, and very young children should not be allowed to creep around on the floor. They scraped up the dust with their fingers, which they would afterward put in their mouths. Thus the germs which settled on the floor were conveyed to the sensitive membranes. The experiments of Gebhardt, of Bonn, had shown that false membrane could be dipped in a sublimate solution, and then, after drying and teasing, cause a bacillus development in a culture medium. It was therefore especially under the conditions of diphtheria, slow in germicidal action, but thorough, if once brought into perfect contact with the affected areas. A five per cent. solution of acetic acid had been shown to be quickly penetrating.

Cervical Adenitis.—DR. B. T. SHIMWELL, of Philadelphia, read the paper. Lymphatic stasis was present to a greater or less degree in the majority of children, and was a local manifestation of a general disease. The glandular enlargement resulting therefrom later caused the surrounding cellular tissue to become affected. Caseation is more common in, though not entirely dependent upon, the so called "scrofulous" diathesis. In these cases there is often deep-seated pus, when there

may seem to be only superficial cervical swelling. A proper understanding of the anatomy and relations of the cervical fasciæ were necessary for proper surgical treatment. Poultices he strongly condemned. The knife should be used early. General tonic treatment was presupposed. Hilton's method of opening the abscesses should be followed. Thorough irrigation and breaking down all pockets with the finger were necessary. No compresses should be used. If bichloride was used, it should be followed by irrigation with some other fluid. He had used the silico fluoride of soda with much satisfaction. The shock in all operations about the neck was disproportionately great.

Tetanus Neonatorum.—Dr. B. A. Waddington, of Salem, N. J., read a paper on this subject. In a practice of twenty-six years he had had eight cases with two recoveries. Seven were among negroes. His cases had always occurred under bad sanitary conditions. He believed the disease to be due to a specific coccus. He had had no recoveries with chloroform, calabar bean, small doses of chloral, or Sims's method of manipulating the parieto-occipital bones so as to lessen pressure on the medulla. In both of his favorable cases he had found a filthy condition of the navel. This he had cleansed with beta-naphthol and peroxide of hydrogen solutions, and had then given beta-naphthol and chloral in hourly doses of one grain each, diminishing as the convulsions lessened.

Dr. A. Behrend, of Washington, D. C., believed the cause to be pressure on the medulla. He regarded chloral as a specific if pushed.

Report of Thirty-five Cases of Pharyngeal Diphtheria Treated by Sub-membranous Injections, was the title of a paper read by Dr. A. Seibert, of New York, who demonstrated the use of the methods employed. His instrument was virtually a hypodermic syringe, having a long nozzle terminating in a hollow plate. At right angles to the latter were several very short ordinary hypodermatic needles not over one-eighth of an inch long. The long nozzle could be bent on its axis at various angles, so as to fit the different portions of the throat. His fluid was the aqua chlori of the United States Pharmacopeia. Pharyngeal diphtheria was at the start always a local process. The bacilli gained access to the deeper mucous layer alone, or with streptococci, causing the exudate. The false membrane was to be regarded as the result of this action rather than as the disease itself. Our treatment should be local, so as to kill the bacilli early, before they became so deeply imbedded as to become beyond the reach of our antiseptic fluids. Giving bichloride by the stomach was useless. To remove the membrane and rub in the same solution hurt the sound epithelium, and the bacilli were thereby only rubbed deeper into the tissues. Chlorine water (from one-quarter to one half a syringeful) was easily injected over the minute spots which were seen during the early stage of the disease. In only one case had the gag been required. The chlorine was penetrating and attacked bacteria and all organic matter. It was better to inject deeply. It was believed that where the membrane was of a dirty, sloughing nature, there were more streptococci than bacilli present. The injections should be made on an empty stomach. The pain was slight. A mouth wash was subsequently used of iodine and carbolic acid, and an ice-bag was placed over the neck. Food and stimulants were given as usual. While during the day the child might be disturbed frequently for the various procedures necessary, it should be allowed to remain undisturbed from midnight till 6 A.M. All of his cases were at least three days old. The membrane remained for from two to four days, but it came away mechanically under the influence of the mouth wash. He had lost only two cases out of the thirty-five, one from heart failure and tracheo-bronchial diphtheria which had come on before he saw the case, and the other had been improperly treated by the attendants. Cultures made in ten cases showed the Loeffler bacillus in each instance. Not one of the favorable cases had any subsequent paralysis, because the early germicidal action of the remedy prevented ptomaine formation.

Infant Dress.—Dr. F. S. Parsons, of Boston, Mass., read the paper. The present method of wrapping newborn babies up like mummies is wrong. The belly-band constricts the abdominal walls and prevents their natural elastic resiliency. It predisposes to rather than prevents hernia. The garment next to the skin should have sleeves and legs so as to allow free movements of all the extremities and should be perfectly loose. Over this can be put whatever is necessary for warmth and protection.

The following papers were referred to the publication committee: "Lithæmia in Children," by Dr. William Pepper, Philadelphia, Pa.; "Prevention of Pulmonary Phthisis in the Adult by Proper Treatment of the Lung Lesions of Childhood," by Dr. W. N. Stickler, of Orange, N. J.; "The Pathological Aspects of Phimosis in Children," by Dr. C. N. Dixon Jones, of Brooklyn, N. Y.; "Sympathetic Convulsions in Children," by Dr. S. J. Radcliffe, of Washington, D. C.; "Remarks on the Child's Ear," by Dr. Samuel Sexton, of New York.

The following gentlemen were elected officers of the Section for the ensuing year: *Chairman*—Dr. E. F. Brush, of Mt. Vernon, N. Y.; *Secretary*—Dr. B. A. Waddington, of Salem, N. J.

OBSTETRIC SECTION

Fourth Day, Friday, May 8th.

The Restoration of the Pelvic Structures after Injury, was the subject of a paper by Dr. Henry O. Marcy, of Boston. The doctor's views on the lesions of the perineal structures and the reconstruction of the various parts involved, are in a general way well known to the profession. His methods are widely different from those usually commended, and in a synoptic way may be classed as follows: The parts injured lie behind the vaginal muscle, and the dissection should be so made as to lift it forward. The retroverted ends of the transversi muscles are thus reached and rejoined to the levator loop. This is accomplished by buried tendon sutures applied in different lines, and the parts thus closed are sealed with iodoform collodion. When the rupture is complete the rectal and vaginal sides are first closed by lines of continuous buried tendon sutures, and then the operation is finished as when the rectum is not involved. Dr. Marcy has used this method for many years, and has operated on several hundred cases, without a perfect restoration of the parts. Trachelorrhaphy is greatly simplified by the use of the continuous tendon suture applied with the Hagerdon needle, and the great gain lies in the fact that the sutures require no further attention, and a vaginal dressing of iodoform wool changed once or twice is the sole care that is requisite. Thus effected it allows of a perineal reconstruction, at the same time operation, also a manifest advantage. Dr. Marcy always uses the continuous tendon suture in the closure of vesico-vaginal fistula, and in vaginal resections undertaken for cystocele, or other deformities of the tract requiring plastic operations. The paper included an interesting review of the uses and history of the animal suture.

Thirty-five Specimens of Ectopic Gestation Removed Post Mortem, was the subject of a very able paper by Dr. Henry F. Formad, of Philadelphia. The paper contained a large amount of statistics. The doctor had examined 3,500 women, many of them, however, quite old women. His 35 cases were: 1 ovarian, 3 interstitial, and 31 tubal intra peritoneal. The ages of the women were from twenty to forty years. They were women in good health and hard working women. They were all multiparæ, and all at the time under some form of physical emotion, working, lifting. Not one of the cases was diagnosed ante mortem; 31 died in 12 hours and 3 in 21 to 36 hours—the three interstitial cases. All of these

women knew they were pregnant. There was a bloody discharge, a sudden pain in the abdomen, a giving way, and collapse. Mode of death in every case, internal hemorrhage. He thinks there is no such thing as hæmatocele of the Fallopian tube. He thinks he must have missed an enormous number of cases of ectopic pregnancy in former years. He used to find a number of cases of hematocele; he believes now they were ectopic gestation. He found it a very hard matter to find the fœtus, and only succeeded in one half of the cases. In all of his cases there was chronic salpingitis.

The Pathology and Treatment of Chronic Ovaritis, was the subject treated by Dr. A. J. C. Skene, of Brooklyn, N. Y. He discussed the great question when to remove the ovaries and when not to. Young persons he found to stand removal of the ovaries badly. They became fat, irritable, indolent, and dissatisfied. His treatment for chronic ovaritis was saline laxatives, relieve pain by bromide of sodium 20 to 30 grains with fluid extract of hydrastis 10 to 15 drops. This is most efficient in the beginning of the attack. If the pain returns, may return to the medicine, ten grains of salicylate of soda and five of antipyrine between meals, and at bed-time when the stomach is empty. Give feeble patients aromatic spirits of ammonia and camphor, which are better than alcohol. In unmarried avoid local treatment if possible. Use hot sitz baths. Bichloride of mercury and syrup iodide of iron are good. The bromide may be supplanted by sulphonal if found insufficient.

Cœliotomy (Abdominal Section) for Rupture of the Parturient Uterus was the subject of a paper by Dr. Henry C. Coe, of New York. The doctor thought this pre-eminently a surgical emergency, and should not be studied from its gynecological or obstetrical side alone. The author based his paper entirely on his own personal experience, that of four cases in which abdominal section was performed, one case successful, the patient being now in perfect health. Operative treatment in the unsuccessful cases came too late, *i.e.*, from eight to eighteen hours after rupture. The successful case was as unfavorable as could be, but was operated upon early, as soon as the lesion was discovered. The writer thinks that abdominal section is indicated under the following conditions: Before the uterus is emptied, when the placenta or any portion of the fœtus has escaped through the rent, as attempts at manual delivery only increase the shock and destroy the patient's chances after section; where there is evidence of progressive internal hemorrhage. After the uterus is emptied it should be done when there is extensive prolapse of the gut through the tear. In all complete lacerations (especially in those involving the broad ligaments), except small tears low down near the vaginal fornix, where good drainage can be maintained. In incomplete tears where the broad ligament is extensively involved and there is evidence of progressive hemorrhage, this point must remain *sub judice*. Only one other besides the writer (Peters) has opened the abdomen in such a case. After opening the abdomen he arrests the hemorrhage, either with the forceps or the temporary rubber ligature. If the tear is small (two inches), and is low down in Douglas's cul-de sac, drainage per vaginam may be indicated. If the tear is clean cut without contusion of the edges, and does not involve cervix or broad ligaments, it may be closed with deep or seroserous sutures. If the tear is not low down, is extensive, with contusion of the edges, and especially if a portion of the fœtus presenting protrudes, amputation of the uterus with extra-peritoneal treatment of the stump is indicated. In extensive transverse tears of the lower segment of the uterus, and in tears beginning in the cervix and extending upward through the broad ligament, the writer would strongly urge the propriety of total extirpation of the uterus as the operation par excellence. The doctor deprecated any intention of recommending a heroic method of treatment to the entire exclusion of the more conservative. He is an avowed conservative in abdominal surgery, but believes that rupture of the parturient uterus is a desperate emergency, in which a fatal termination is the rule, and that it requires prompt and energetic treatment according to the rule of modern surgery. The fact that statistics of cœliotomy in these cases have shown a large mortality is not an argument against the operation. In every case the accoucheur, if not himself a surgeon, should, without an instant's delay, summon experienced counsel, and explain to the family that immediate resort to the abdominal section may be necessary. Only by prompt interference can we expect to improve statistics, and thus elevate the operation above the level of a hopeless and apparently unnecessary surgical experiment.

The Use of Vaginal Tampons was the subject of a paper by Dr. W. A. R. Sellman, of Boston. He thought the vaginal tampon was seldom required for a hæmostatic effect. In an experience of twenty years he has not found it necessary to tampon for a hæmostatic effect for hemorrhage. He did not even favor the tampon in hemorrhage from cancer. He never applied the tampon in specific gonorrhœa, as it might force the disease up into the uterus and tubes. He recommended tampons in office practice, where a solution was applied which might run out and cauterize the outer part. He also recommended them in prolapsed uterus where there was no uterine catarrh, and inserts them as pessaries after plastic operations on the vaginal wall.

My Fourth Conservative Cæsarean Section, was the subject of a paper by Dr. H. A. Kelley, of Baltimore. The patient was dwarfed and rachitic, thirty-five years of age, weighing one hundred and fifteen pounds, and fifty-two inches high. Head large and angular with prominent forehead; body long and legs short, with marked outward curvature of the thigh-bone, giving a distinctly waddling character to the gait. The previous history had been illumined by the fact that she had been paralyzed for a long time, beginning in her eighth or ninth year. She had never grown any after that. The child was taken out alive, and is still living and doing well, as is also the mother, who recovered without an untoward symptom. The details of the operation are given. This makes the fourth case for the doctor in three years, all the patients being alive and well at the present time.

The Use of Cocaine in Gynecological Surgery, was the title of a paper by Dr. William H. Humiston, of Cleveland, O. He uses it in dilating and curetting, first giving a tablespoonful of whiskey or brandy. Fill a hypodermic syringe full of a four per cent. solution, with two minims of pure phenol to each half ounce of the solution; inject five minims into the posterior lip, wait two minutes, then, with the bullet forceps, which will be painless, secure a firm hold. Inject into several portions of the cervical canal an amount equal to about twenty minims; dilate till you can inject ten minims of a ten per cent. solution into the uterine cavity. He has not given an anæsthetic, save cocaine, in dilating the uterine canal for the past three years, and his operations have included many primiparæ. In trachelorrhaphy inject the angle and surfaces you wish to denude, and you can operate with no pain at all. In perineorrhaphy he uses the split flap operation, and with one injection of thirty to forty minims of a four per cent. solution, he anæsthetizes the whole field. He quiets his patients by telling them he will give them chloroform if they cannot stand it, but has never had to do so. Has had unfavorable symptoms from the cocaine, which vanish very quickly after the administration of stimulants. He has dilated the urethra for fissure and irritable caruncle with but slight pain. He had assisted at an Alexander operation where two grains were injected, one in each side, at intervals of one half-hour. The patient experienced but slight pain. He then reported a case where he performed the operation of trachelorrhaphy, anterior and posterior colporrhaphy, and perineorrhaphy, at one sitting, with cocaine as an anæsthetic. The whole time required in making the four operations was but one hour and forty-

five minutes, and seventy-five minims of a four per cent. solution of cocaine was used, or three grains.

Minor Uterine Surgery was the title of a paper by Dr. J. M. Baldy, of Philadelphia. He thought that Emmet's operation for lacerated cervix should in most cases fall into that deserved disuse which has come to splitting up the cervix for sterility and dysmenorrhœa. He thinks, on the whole, it had been better for womankind had the uterine sound never been invented. He thought the careful study of bimanual palpation would largely do away with the sound. Taking it all in all, he decidedly approves of gynecological minor uterine surgery in the field to which it is applicable, but it must be borne in mind that this field is a limited one, and one which becomes more and more narrow as our diagnostic resources increase.

A Contribution to the Normal and Pathological Histology of the Tubes, was the subject of a paper by Dr. J. Witridge Williams, of Baltimore. He insisted there were three layers of muscular tissue instead of two. A twisted condition of the tube, he said, showed the border line between health and disease. The twists show an infantile condition of the tubes. This is found in women who are poorly developed sexually, and may be accompanied by sterility. The paper was accompanied by a number of well executed charts.

A Study of Infection through the Drainage-tubes, was a very scientific paper read by Dr. T. A. Robb, of Baltimore. The experiments were carried on in the laboratory of the Johns Hopkins Hospital, and showed an infinite amount of work on the part of the essayist.

The paper was discussed by Dr. Kelley, on whose patients the experiments had been performed, and who complimented the work very highly.

The Treatment of Posterior Face Presentations, was a paper read by Dr. Eugene Bernaday, of Philadelphia. It has been his experience that if the chin presents posteriorly at the commencement of labor and engages in the superior strait as such, unless changed by manual interference, there remains a posterior position during labor. The treatment of mento-posterior presentations practically resolves itself into two methods, version and craniotomy. He has failed to obtain any good results from the use of the vectis. The forceps should never be applied when the chin is to the sacrum. This is invariably followed by serious injuries to the mother without due compensation. Version should only be performed when the presenting face has passed out of the mouth of the uterus. After the face has entered the pelvis I consider all attempts at version unjustifiable. Should all attempts fail to produce a favorable change in the presenting face, craniotomy should be performed, not after hours of ineffectual labor, when the mother's tissues are sodden and their vitality destroyed by the continuous pressure of an impacted face, but should be done at once.

Pyoktanin as an Antiseptic, was the subject of a paper by Dr. H. J. Boldt, of New York. The doctor has given this remedy a thorough trial, though only for a short time, but has been very favorably impressed with it. The suppuration ceases more rapidly under its use than under other remedies, and that without producing any noticeable effect on the system. He used a one per cent. watery solution, which is five to ten times stronger than is recommended. He has used it with success as an intra-uterine medicament.

A Case in Obstetrics, Followed for Months by a Daily Discharge of over Two Quarts of Watery Fluid through the Cervical Canal, was the subject of a report and paper by Dr. John Hammond Bradshaw, of Orange, N. J. The child was a male, weighing 12.5 pounds, with a large ossified head, face presentation, podalic version, and child born dead. The sound, on examination some weeks after labor, passed readily through the fundus of the uterus to an almost limitless extent. The patient, finally, after being placed on codeia, recovered from the flow, which commenced again on discontinuing the remedy, and again disappeared on resuming it. He is of the opinion, after six months' observation, that this fluid comes from the peritoneal cavity, and that there is existing a hole through the uterine wall.

There were quite a number of other papers, read by title or in full.

The officers elected for the ensuing year were: *President*—Dr. E. E. Montgomery, of Philadelphia; *Vice-President*—Dr. Bedford Brown, of Alexandria, Va.; *Secretary*—Dr. Franklin H. Martin, of Chicago.

On motion of Dr. Thomas Opie, of Baltimore, the number of papers at future sessions was limited to forty, and the Chairman was given power to eliminate to reduce to that number. There were seventy papers offered this time, and it was impossible to hear them all, though many were read by abstract.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

DISCUSSION AT THE MEDICAL AND CHIRURGICAL SOCIETY ON THE VALUE OF TUBERCULIN IN SURGICAL TUBERCULOSIS—REJECTION OF THE DRAFT CHARTER FOR THE UNIVERSITY OF LONDON.

London, May 16, 1891.

A special meeting of the Medical and Chirurgical Society was held last week in order to discuss Mr. Watson Cheyne's paper on the value of tuberculin in surgical tuberculosis, read at the preceding meeting of the Society.

Mr. Barwell opened the discussion, and his views as to Koch's treatment were very pessimistic. He pointed out that the fluid contained not merely sepsin but also one per cent. of an alkaloid which was very poisonous, and was probably a ptomaïne allied to sepsin. It was manufactured in the culture medium by the growth of the tubercle bacillus, and there was as yet no known means of equalizing the quantity of this alkaloid in Koch's solution. Koch's fluid, again, did not deprive the bacilli of their infective properties, and Virchow was of opinion that it was liable to produce general tuberculosis. Mr. Barwell said he agreed with the last conclusion. He then pointed out that the results published in this country could be summarized as follows: Mr. Hutchinson had not seen one case of lupus cured; of Dr. Heron's thirty-four cases, four were worse, nine stationary, and the rest were improved. Mr. Cheyne's lupus cases were remarkable. One—apparently cured last December—had relapsed in a month; of the rest, not one was cured, even with the aid of vigorous surgical treatment.

Dr. Douglas Powell said he must admit that he had been disappointed with the results of the treatment. He had not, however, seen any of the terrible catastrophies one read of. In only one case had an excessive reaction given him cause for anxiety. In one other case there was danger of pyæmia. Mr. Cheyne considered sepsis to be a contra-indication, but the chief incidents of the second stage of phthisis were due to the material which was in the cavities undergoing septic change. These incidents were necessary accompaniments, and it was needful to sustain the patient's strength through this eliminatory period, and then the means adopted for this purpose were often successful. It was certainly possible by means of tuberculin to hasten this period of elimination, and the question then arose as to what cases it would be safe to do so in. This could only be decided by experience. He doubted if Mr. Cheyne's method of frequent inoculations was adapted for the treatment of internal tubercles, as it was impossible to provide efficient drainage, etc. The result of frequent injections seemed to be to stimulate the tissues to throw off the tuberculous stuff and to get the better of any left behind. The natural effect of the stimulation of the healthy tissue was to bring about fibroid change, which was the natural safeguard against the

further spread of the tubercle and the natural accompaniment of its arrest. The use of inoculations for too long a period or too often might hinder the formation of fibrous tissue.

Mr. Howard Marsh said everybody was anxious to know if the remedy would be able to deal single-handed with tubercle—as mercury could with syphilis—or if it was a useful accessory to other forms of surgical treatment. Mr. Cheyne had apparently concluded that it was not a specific, as his advice was not to adopt it in an early stage of the disease. If it was not an efficient remedy against incipient disease, there was but little chance of its being so in the later stages. Was tuberculin then a useful accessory in combination with other methods? Mr. Marsh pointed out that in the treatment of tuberculous joint diseases surgeons were divided in opinion as to which of two courses to adopt. One method was the expectant one and he employed this himself. The other was an early and free removal of the diseased tissues by operation. He thought tuberculin might possibly help to circumscribe the extent of these operations.

Dr. Delépine showed a few specimens which he had obtained six years ago from tuberculous synovial membranes in which the appearances exactly resembled those which Mr. Cheyne had exhibited at the last meeting, from cases treated with tuberculin, and which he had contended were the result of ordinary inflammatory processes.

Dr. Hime said he differed from Mr. Barwell in thinking the general reaction produced by tuberculin was similar to the effects of septic infection. The curative results obtained both here and abroad were, he thought, very gratifying.

Dr. Theodore Williams said his own experience was most disappointing. All his cases in which the treatment had been tried had done badly, whereas cases in the first stage treated with cod-liver oil and tonics, and sent to sea or to the mountains, got practically cured.

Dr. Abraham thought the results were not equal to the first expectations. There was no relation between the quantity of tuberculous disease present and the reaction, and the latter was of no real diagnostic value. There was little fear of the disease being disseminated by the treatment.

Dr. Drysdale said he had followed both Dr. Heron's cases and those of Mr. Cheyne, and had come to the conclusion that he would not try the treatment himself.

Dr. Wethered referred to cases in which improvement had followed the treatment, and said he thought it ought to be tried. He agreed with Mr. Cheyne that the treatment had been prematurely cried down and its dangers magnified.

Dr. Edward Squire said the matter of dosage was a very important one. In medical cases rapid elimination was not required, but a slow action to allow of the formation of fibrous tissue around the tuberculous patches. In his own cases of lupus improvement was followed by relapse.

Mr. Harry Fenwick said he had tried tuberculin in ninety cases of urinary tuberculosis. The presence of septic processes was very important and very unfavorable. The swelling of the peri tuberculous tissues led to suppression and retention of urine. Hemorrhages had followed the use of Koch's fluid. He concluded that it could only be of therapeutic value in the earliest stage of vesical tuberculosis.

Mr. Watson Cheyne then replied and said that in speaking of sepsis he had only been thinking of pyogenic cocci, and not of the organisms found in phthisical cavities. There was no reason why his method should be irksome, as a nurse could give the injections. That tuberculosis could be kept stationary by the treatment seemed evident by the fact that relapse often followed cessation of treatment. He did not advise the treatment to be used before operation, because tolerance would be established, and so a valuable assistance in the after-treatment would be lost. He agreed with Dr. Delépine that there was nothing specific in the inflammation after the use of tuberculin, but what had struck him so much was the remarkable predominance of the organizing appearances in the tubercles in his specimens. He remarked that physicians had been more excited about this remedy than surgeons, and were always so after fresh remedies against tubercle were announced. This did not look as if cases of early phthisis yielded very readily to ordinary treatment.

On Tuesday evening last the Draft Charter for the reconstruction of the University of London was rejected by Convocation by a majority of more than two to one, the exact numbers being: For, 197, against, 461. The division was preceded by an animated debate in which most of the arguments were put forward with which we have long been familiar. The supporters of the scheme made a great point of the fact that, if the Draft Charter were rejected, a new University for London would be founded and the present one left stranded; the latter statement was received with considerable derision. In seconding the motion of Lord Herschell to adopt the Draft Charter, Sir Richard Quain made an Irish bull by observing that, as a graduate of fifty years' standing, he could not be silent without speaking. Mr. Bompas, Q.C., led the opposition against the scheme and, pointing to the diverse conditions under which degrees were (in accordance with the scheme) to be granted by collegiate examinations of varying nature, said that in future the possession of a B.A. would not necessarily show what the holder knew, or that he knew anything. Mr. R. H. Hutton (a member of the Senate) said the new scheme was a kind of centipede; it had an enormous number of ganglia and no cerebrum. Mrs. Scharlieb, M.D., said the women members of Convocation were by a large majority opposed to the scheme. I understood her to say that, if it were carried, women students of medicine would in future seek their qualifications to practise elsewhere. The announcement of the numbers was received with cheers. It is now generally agreed that the scheme is dead and that the coming event is the creation for the metropolis of a teaching university as a local body on the lives of the older universities.

THE ABORTION OF PNEUMONIA.

To the Editor of the Medical Record.

Dear Sir: I have been very much interested in an article written by Dr. Oliver J. Roskoten, of Peoria, Ill., in the Record of May 2d, upon the "Abortion of Pneumonia" in which Dr. R— claims to have aborted four cases out of five by the use of a mixture of jaborandi, acetate of ammonia, and aromatics, with hot pediluvia and counter-irritants. During the last few months I have had occasion to search the literature upon this subject very thoroughly, and the only case I have found of the apparent abortion of pneumonia is one reported by Dr. H. E. Counsell in the London *Lancet* for 1889, vol. 1, page 730, in which the writer claims to have aborted pneumonia in its first stage by a single dose of fifteen grains of antipyrine. In this case, if I remember correctly, hot pediluvia had been used before the drug was administered.

In a paper which I had the honor to read at the last meeting of the American Medical Association, in Washington, I have shown from a list of more than three hundred cases which I have treated during the last twenty years that pneumonia in its first stage can be in many cases aborted by the use of hot mustard pediluvia and baths applied to the legs, thighs, arms, and hands, and hot flax-seed or rye-meal poultices, sprinkled with enough mustard to produce a gentle counter-irritation, over the chest. This I believe to be sufficient in many cases to abort the disease, and its action is upon the well-known principle that active stimulation of the venous and arterial capillaries upon the surface of the body and at the ex

tremities always equalizes the circulation of the blood and relieves and removes internal congestions. I think all writers agree that the first stage of pneumonia is one of active congestion or pulmonary engorgement, and therefore the first indication for treatment should be to diminish the blood pressure by bringing as much blood as possible to the surface of the body and thus equalizing its circulation.

I have never used so dangerous a drug as jaborandi in this disease, but have recently used a single dose of antipyrine, of ten or fifteen grains, immediately upon getting my patient into bed after the mustard bath; but I seldom repeat the dose, as I have found the repetition apt to produce nausea and great depression. My treatment has usually been very simple, consisting, with an adult, of a powder containing five grains each of nitrate of potassa and Dover's powder, which may be repeated in three hours if free perspiration does not ensue; fifteen minutes after giving the first powder I give from one half drop to one and one-half of tr. aconite rt., combined with fifteen drops spirits æth. nit. and water to a teaspoonful. These doses I repeat every half hour until six or seven doses have been given, and then give at intervals of one or two hours. I keep my patient well covered to the neck with an extra quantity of bed clothing and have the feet kept hot with a rubber bag or jug filled with hot water. After two or three hours I find him in a profuse warm perspiration; the headache and blood-pressure upon the lungs are gone and the temperature and pulse begin to go down, until in the course of twenty-four hours they are nearly normal.

Now, Mr. Editor, in twenty years' practice I have used this treatment in several hundred cases and found it practically successful; so much so that I have seldom failed to abort a case that has not got to the second stage; but there is one very serious obstacle in its way, and that is the difficulty in persuading physicians to adopt any such simple plan of treatment as I have described. They will run after and spend hundreds of dollars in experimenting with the delusions and fallacies of a Brown-Séquard, or a Koch, while common-sense principles and treatment are entirely overlooked. I believe it to be utterly useless to look for a single drug that will sweep congestion and engorgement out of lung-tissue, for it will never be found until one is found that will repair a broken bone or sew up a wound. But the disease must be met and fought on common-sense principles, and in that way can be cut short very easily if proper treatment is used at first and patiently persisted in. I believe, with the editor of this journal, that "the treatment of this disease is still a reproach to our art;" and it is so because physicians expect too much of the drugs they administer. I would like to notice very fully many methods of treatment which I have seen used, but time and space will not permit. One of the worst is the continued administration of opium, which simply relieves the pain but allows the inflammation to run an unbridled course. Another is quinine, which has been proved times without number not to act as an abortifacient but to derange the appetite and digestion, produce cardiac weakness, profuse cold perspiration, and profound nervous debility. I might also mention the treatment with veratrum viride and calomel, the effect of which can only be to somewhat reduce the temperature and modify the disease. Digitalis, indeed, is a cardiac tonic and stimulates the circulation of the blood to the capillary blood-vessels, but its action is not sufficient to remove the active congestion, as it cannot be used in large or frequently repeated doses. Venesection, too, though it may be useful at the very first, is too dangerous a remedy to be thought of when the disease has made any progress.

It is my opinion that physicians will never be able to successfully abort this disease until they learn to go back to common-sense principles and use common-sense treatment, even if it has not the sanction of a *savant* or college professor.

J. W. Small, M.D.

153 East Fiftieth Street.

ALOES—A CORRECTION.

To the Editor of the Medical Record.

Sir: Referring to my paper on aloes which appeared in the issue of the Medical Record for December 6, 1890, I beg leave to correct the formula for the "Weisbaden Elixir," which, owing to the absence of the original, I gave from memory, expecting to make the necessary corrections when proof came to hand. Unfortunately the matter was overlooked, and the formula, as published, is defective. I am prompted to make this statement because of the numerous applications I have had from manufacturing chemists to have me approve of the pills, capsules, etc., which they had taken the trouble to prepare for the purpose of supplying physicians with this product. The original formula, as written by the Wiesbaden physician, is as follows:

℞	Spanish saffron	gr. xx.
	Socotrine aloes	ʒ j.
	Boletis laricis	ʒ j.
	Powdered myrrh	ʒ jss.
	Powdered rhubarb,	
	Powdered angelica root	āā ʒ ij.
	Zedoary root,	
	Gentian root,	
	Calamus root	āā ℥ ss.
	Brandy	♁. ij.

M. Sig.: Eight or nine drops to be taken half an hour after meals, on sugar, or mixed with a little brandy or wine. Cold water must not be taken soon after the medicine.

At the time this formula was published I suggested that it would be found convenient to have it dispensed with a little glycerine, because water causes a precipitate. A little wine may be substituted unless there be objections from a moral stand-point, but I think this can be effectually met by having the product evaporated and presented in the form of a mass, either in pill or capsule, or it might be enclosed in wafers to suit the taste of the patient. I beg leave to say in this connection that the remedy is very much improved by age, and it will be found in practice that stock six months old or more will be more satisfactory than that which has been freshly prepared. For all practical purposes, both the saffron and myrrh may be omitted, and if the product is put up in the form of a solution the elimination of these ingredients adds greatly to its appearance. It will be superfluous for me to add any suggestions in regard to the care which should be exercised in selecting the different drugs included in this combination, and it will not be necessary to point out the need for the most thorough and long-continued maceration, in order to secure the active principles together with the peculiar aroma characteristic of this excellent preparation. Instead of brandy, I think diluted alcohol would answer the purpose quite as well when the product is intended for use in the solid or semi-solid form; but when it is to be used in the form of a liquid, I much prefer the brandy; it can then be given alone or in combination with a simple tincture, as gentian, calamus, or cinchona.

It will be observed that aloes is the only active purgative remedy, the other ingredients in the doses used being principally carminatives, and as the dose of aloes is sufficiently large, I hope no one will so improve upon the original as to substitute purified aloes, or aloin, the active principle. There can be no doubt in the minds of practitioners familiar with the facts, that irreparable injury attends the attempts on the part of physicians and the laity to secure active purgative effects from the continued use of aloes, and I repeat here what I hinted at in the paper referred to, that many a case of Bright's became possible only through the abuse of aloes or other similar purgative. When it is stated that the now popular pill containing aloes, strychnine, and belladonna, is made by manufacturing chemists who are not supposed to be doing a very extensive business, in lots of one million at a time, we can have some conception of the immense number of these that are yearly consumed. While admitting

that the combination is efficient, the marked increase within the past few years of kidney troubles seems to be in close relation with the popularity of the pills referred to, and I hope the medical profession will take the necessary steps to arrest this demoralization, and put a stop to the destruction which unwise medication is producing.

Another suggestion might be added, viz.: That the Wiesbaden elixir in the form of a bolus could be advantageously combined with ox-gall, which, as is well known, has a favorable effect when exhibited in combination with aloes. Ox-gall, moreover, supplies an artificial antiseptic, assists in the digestion of fats and starchy food products, and thus serves to prevent the formation of poisonous products in the intestine. I have no doubt but that a combination of this character would be found useful in a very large number of cases where aloes is indicated, and think it is but a question of time when a combination of this nature will take the place of aloin, strychnine, and belladonna. Very respectfully,

JOHN AULDE, M.D.

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from May 20, 1891, to May 30, 1891.

WELLS, GEORGE M., First Lieutenant and Assistant Surgeon. By direction of the Secretary of War, will proceed from Paoli, Ind., to Columbus Barracks, O., and report in person for duty to the commanding officer of that post. S. O. 115, par. 7, A. G. O., Washington, D. C., May 20, 1891.

WYETH, MARLBOROUGH C., Captain and Assistant Surgeon. By direction of the Secretary of War, is granted leave of absence for three months on surgeon's certificate of disability. S. O. 119, par. 6, A. G. O., Washington, D. C., May 25, 1891.

BROWN, PAUL R., Captain and Assistant Surgeon. Granted leave of absence for one month, with permission to apply for an extension of one month. S. O. 59, par. 4, Department of the Missouri, May 26, 1891.

Official List of Changes in the Medical Corps of the United States Navy for the week ending May 23, 1891.

BRIGHT, GEORGE A., Surgeon. Detached from the Omaha, and granted three months' leave of absence.

MEANS, V. C. B., Passed Assistant Surgeon. Detached from the Omaha, and granted three months' leave of absence.

KEENEY, JAMES F., Assistant Surgeon. Ordered for examination preliminary to promotion to Passed Assistant Surgeon.

Cotton Mather as an Inoculationist.—Cotton Mather, the much-abused Puritan divine, nearly lost his life in the advocacy of inoculation. He succeeded in converting Dr. Zabdiel Boylston to his views, but the chief "society doctor," Dr. William Douglas, opposed inoculation by arguments of the familiar anti-vaccination stripe. Dr. Boylston inoculated his negro servants, whereupon an attempt to lynch him resulted, and absortive attempts were also made to blow up Cotton Mather's house. Seventy-eight years later, when Dr. Waterman introduced vaccination, the same physical arguments were used. Variola epidemics in which the immunity of the inoculated and vaccinated were demonstrated, saved Drs. Boylston and Waterman from violent deaths at the hands of a mob excited by newspaper and society demagogues.—*Medical Standard.*

Rötheln	0	0

The Dwelling-house in Relation to Tuberculous Consumption.—In an article on this subject, in *The Practitioner* for February, 1891, Dr. R. Thorne summarizes the conditions of dwellings tending to the promotion and to the prevention of tuberculous consumption as follows:

Conditions tending to the promotion of consumption:

1. A soil either (*a*) naturally damp and cold; or (*b*) subject to the influence of the rise and fall of a subsoil water lying within a few feet of the surface.

2. A dwelling-house of which either the foundations, the area they enclose, or the walls, are, by reason of faulty construction or otherwise, liable to dampness.

3. Such immediate surroundings of the dwelling-house as tend to prevent the free movement of air about it, and its ample exposure to the influence of sunlight.

4. Such structural defects as would prevent the maintenance within all parts of the dwelling-house of ample movement of air by day and by night, and free exposure of its habitable rooms to daylight.

Conditions tending to the prevention of consumption:

1. A soil which is dry (*a*) naturally; or (*b*) freed by artificial means from the injurious influence of dampness, and of the oscillations of the underlying subsoil water.

2. A dwelling house so constructed as to be protected against dampness of site, foundations, and walls.

3. Such open space on at least two opposite sides of the dwelling-house as shall secure ample movement of air about it, together with its free exposure to the influence of sunlight.

4. Such construction of the dwelling-house as will secure for its habitable rooms and throughout its interior free movement of air by day and by night, and the free access of daylight.

Coddling.—The following, from the pen of the "Woman about Town" in the New York *Evening Sun*, is a suggestive, as well as entertaining, bit of newspaper prose: "A melancholy tale of a small boy was told recently to The Woman—a tale whereby hangs—not another story—but a small, very small, sermon. Here is the tale: This small boy was the child of an intelligent, a super-intelligent mother, who had all kinds of beautiful theories about small boys and the way to rear them hygienically. From his babyhood, therefore, this boy had been brought up on theories. From the time he was promoted from baby foods—of which he was allowed to have only the most improved kinds—he never had the fun of eating any of the awfully unwholesome and awfully good compounds that do so much toward keeping the average boy from wanting to be an angel before his time. He never ate pie and pudding and hot biscuit and maple syrup and taffy and green apples and popcorn all at once, and he never had a howling stomachache which he could ease only by swearing a little when his brother was around and his mother wasn't, and then crying a little, in between, when nobody was around. No; he was allowed to eat only the simplest foods—oatmeal and a little meat and some potatoes and healthful whole-wheat bread and all the things that the books tell about. And so he lived and grew, in spite of it all, until he was about eight years

of age, and then he went to make a visit to his grandmother, who wasn't 'advanced' or highly informed as to the new ideas in dietetics, but who was old-fashioned and had queer ideas that boys like good things to eat, just for the sake of eating them. And so she sat up nights to think of good things for this boy to eat. And he—well, he forgot all about his 'bringing up,' and it is to be feared that he sat up nights, too, to eat some of the good things she stewed up for him. This beatific state of things lasted a whole week, and then something serious occurred. The small boy grew suddenly and dangerously ill. His grandmother poulticed and dosed him with just the same old-fashioned enthusiasm with which she had fed him. But he hadn't been accustomed to heroic treatment of any kind, and in two days he died. That's the story. The moral is this—it isn't pointed, you will observe, either at the grandmother or the boy, but at the mother. The Woman lays the blame for that boy's death right at the mother's door. She had brought the youngster up on too improved methods. She had coddled his stomach and made its work easy for it until it had never developed half its normal strength and ability to take care of food. And the first time it found a heroic task set for it, it gave it up altogether. Stomachs are not unlike people. They need hard things to develop them sometimes. Lobster and Welsh rarebit and ices at unholy hours have their purpose in the physiological world just as well as dumb-bells and rowing machines and chest weights. Trust the stomach to tell you when you have carried your heroism too far. But don't make a molly-coddle of it, or it will make a dyspeptic or a corpse out of you. There is sound sense and real wisdom in the voracious but ungodly taste which prompts the small boy to make an ostrich of himself. Let him do it if you want to make him strong."

The Prevailing Fevers of China.—Dr. Coltman, writing in the *Medical Missionary Journal* upon the fevers of China, remarks that but little personal investigation on the subject has been made up to the present time, owing to the comparatively recent advent of foreign medical men, and to the want of confidence on the part of natives to submit for any lengthened period to the treatment of a foreign physician, or, in fact, to any one physician, their rule being to change doctors two or three times a day if they can afford it. Again, there have been but small hospital facilities for studying fevers, and there is an impossibility of obtaining post-mortem examinations. Dr. Coltman considers that small-pox is the most common disease, nearly every person suffering from it at some period of his or her life. Vaccination, although practised, is done very carelessly. Measles appear to be common, but is somewhat milder than in Europe. Scarlet fever, although it undoubtedly occurs among the natives, is far less common than among Europeans. Erysipelas is rare. Typhoid fever is very difficult to diagnose in the short time that a foreign medical man is allowed to attend a case; but Dr. Coltman thinks that when more accurate reports are possible, this disease will be found to be more common among the natives than is now supposed. Typhus fever is met with all over North China, and as far south as Shanghai. Relapsing fever is found constantly associated with typhus. Dengue does not seem to be known among natives. Cholera occurs as an epidemic every few years, and is very fatal. Diphtheria is severe and frequently fatal among the natives. Whooping-cough has occasionally been met with. Rheumatic fever is very prevalent in some parts. Chronic muscular rheumatism is common all over China, but is unattended by fever. Malarial fevers appear to be common everywhere, though the prevailing type varies; thus, tertian is most common in Pekin, quartan in Foochow, Swatow, Shanghai, and Hangchow, and remittent in Cheefoo and Tientsin. In Chinanfu, Dr. Coltman has never seen a case of quartan ague; it is all intermittent of the tertian or quotidian type. The treatment, of course, of all malarial fever is by quinine or some other cinchona bark alkaloid. In Hangchow the carbolic acid and iodine treatment has been used successfully as a prophylactic; arsenic is recognized as valuable in the chronic form.—*The Lancet.*

Professional Secrecy and Life Insurance Certificates.—The French Court of Appeal has just delivered judgment in a case in which a widow had brought an action against a life assurance company for the amount of her husband's policy, which the company declined to pay because the medical man who had attended him refused to fill up the usual form with the name of the disease and its duration, declaring himself bound by the law of professional secrecy not to reveal the nature of his patient's disease. The court has decided against the company, holding that the medical man himself is the sole judge as to whether facts revealed to him by a patient were confided to him under the seal of professional secrecy.—*The Lancet.*

A Blessing Upon New York Gynecologists.—I wish to say that the gynecologists of New York are courteous, kind, and obliging. They are progressive and able men, and I am proud of them. As the winters come and go, and the snow-flakes whiten their silvery locks into a crown of glory, may their lives go gently and slowly on. May they many times and oft yet see with healthy eyes the yellow stacks of ripened grain and the straw stack's gleam of gold. May their eyes behold fat, sleek cattle wander ing over rich green pastures. May their ears often listen to the rustle of the silken tassels on the corn. May each returning autumn fill the cup of life's pleasure with its luscious, ripened fruit, and every winter of discontent be scattered by the golden sunshine of repose.—Dr. F. B. Robinson, in the *North American Practitioner.*

The Involuntary Accomplice.—A very good story is told of the celebrated alienist, Legrand du Saulle. A fashionably dressed lady called on a Palais Royal jeweller, and having selected a bracelet of considerable value, requested the tradesman to send along with her an employee in order that she might show the bracelet to her husband and obtain his approval and the money to pay for it. This seeming fair enough, her demand was complied with, and the pair adjourned—to the house of Legrand du Saulle. She went into the doctor's consulting-room under the pretext of showing her husband the bracelet, leaving the employee in the waiting-room. When there she told the doctor that she had with her a young nephew of hers who had a singular monomania, that of believing himself to have been robbed of a valuable bracelet, and she asked the doctor to examine him in another room and report to her thereon. She thereupon left the room in order that the "patient" might be introduced. On entering the room the suspicions of the young man were aroused by the absence of the lady with the diamonds, and he at once insisted upon having either the diamonds or the money. This, of course, was only what Du Saulle expected, and it was some time, and only after a very complicated disentanglement, that Du Saulle began to understand that he had been cleanly duped into acting the part of an accomplice. By that time, alas! the robber had made good her escape.—*London Medical Recorder.*

An Old Story Retold.—Dr. F—— sometimes drank a good deal at dinner. He was summoned one evening to see a lady patient when he was more than half seas over, and conscious that he was so. Feeling her pulse, and finding himself unable to count its beats, he muttered, "Drunk, by Jove!" Next morning, recollecting the circumstance, he was greatly vexed, and just as he was thinking what explanation of his behavior he should offer to the lady, a letter from her was put into his hand. "She too well knew," said the lady, "that he had discovered the unfortunate condition in which she was when he last visited her, and she entreated him to keep the matter secret, in consideration of the enclosed (a £100 bank note)."

ALBUMINURIA IN PERSONS APPARENTLY HEALTHY, AND A CONSIDERATION OF ITS RELATION TO LIFE ASSURANCE.[1]

By WILLIAM B. DAVIS, A.M., M.D.,

MEDICAL DIRECTOR OF THE UNION CENTRAL LIFE INSURANCE COMPANY, CINCINNATI, O.

IN a paper read before the American Medical Association, at its recent session in Washington, D. C., May 6, 1891, I discussed "The Prevalence of Albuminuria among Healthy Persons," and showed from authoritative sources that it is more common among presumably healthy people than was formerly supposed. I called attention to the fact that Professor Grainger Stewart had demonstrated its presence in nearly one third of the population, while Stirling found it in forty-four per cent. of healthy people, Capitan in forty five per cent., De La Celle-Chatauberg in seventy-six to one hundred per cent., and Posner asserts that he has found it in all normal urine.

If albuminuria prevails so widely, and, indeed, if it prevails among but twenty or thirty per cent. of the population, it behooves us to ascertain the cause of its prevalence.

Causes of Functional Albuminuria.—A distinguished authority on Bright's disease — Mahomed — stated that "although a large amount of attention has been devoted to the experimental investigation of the pathology of albuminuria during recent years, our knowledge of it remains very incomplete, and, owing to the contradictory results that have been recorded, what little knowledge we possess appears uncertain." If this be true of the albuminuria of organic disease, which has been known and differentiated for over sixty years, how much more is it true of functional albuminuria? Scarce fifteen years have elapsed since the attention of the profession was first called to it, and during that time a great variety of causes have been reported as producing it.

These may be arranged under the following heads: 1, Dietetic; 2, cold and cold baths; 3, muscular activity; and 4, mental strain and strong mental impressions. The ingestion of food, and cold baths have been active factors in its production.

Dr. Russell, Medical Director of the Ætna Life Insurance Company, has kindly given me a singular illustration of the first subdivision, viz.: A professional friend, who is now and has always been in robust health, has for years invariably found albumin in his urine after eating buckwheat cakes. Dr. Batten found albumin in the urine of four young men after a long ride in a cold railway car. Pavy records the fact that when Weston performed his first pedestrian feat in England and walked one hundred and fifteen miles in twenty-four consecutive hours, his urine, passed an hour after the finish, was albuminous, and contained hyaline and granular casts of the tubules, unaccompanied with blood-corpuscles. Twelve hours later his urine was found to have resumed its normal condition. Dr. Wells, Medical Director of the John Hancock Mutual Life Insurance Company, informs me that a patient of his—a strong, healthy man—always has albumin in his urine after taking a boxing lesson. Johnson reports a number of cases of temporary albuminuria as a result of the fatigue and anxiety of a prolonged examination of the Civil Service. Ralfe said: "Hardly a season passes but I am consulted by some student who has discovered albumin in his urine while reading for his examination, and of whom I hear no further when his troubles are over." Dr. Thomas Bryant, President of the Harveian Society of London, reported a case where a floating kidney was the cause of occasional albuminuria, and Dr. Eastis reported a case of floating kidney in which movement, however easy, caused albuminuria.

Dr. Thorburn, Medical Director of the North American Life Assurance Company, makes mention of excessive smoking as a factor in its production.

Dr. John Mason, in a prize essay read before the Border Counties Branch of the British Medical Association, May, 1890, reports a case of albuminuria at night but not in the day urine. It was found that the presence of albumin depended on certain positions of the body. If the patient lay on the right side or on his back, there were only traces of albumin; if on the left side, there was an abundance of it; if he lay on his belly, there was none.

Dr. Lambert, Medical Director of the Equitable Life Assurance Society, mentions one cause which, I think, no other observer has alluded to, viz., extremes of temperature. In a letter to me he says, "There is one point which has been a constant factor in regard to our examinations in this office. Since 1876 we have examined the urine of everyone applying to this office. When the temperature reaches zero or below, and when the temperature reaches ninety degrees and above, the percentage of apparently healthy men having albumin in their urine increases from two per cent. to five per cent. until the temperature either rises or falls nearer to its mean condition. This has been the result for years in this office every December and January, and every June and July, when the extremes of temperature are most apt to strike the city."

Dr. Burr says that in functional albuminuria it was the circulation rather than the kidneys which was at fault. In these cases there was a weak propulsive power of the heart and deficient vascular tone, the velocity of the blood was diminished and the static condition increased. "The less the velocity and the greater the static condition of the blood, the greater would be the amount of albumin." The question of functional albuminuria, he said, was largely one of physics, and as such should be studied.

Bartels also regards it as due to an altered state of blood-pressure. He says: "Perfectly healthy kidneys, solely in consequence of an altered state of blood pressure upon their vessels, can excrete albuminous urine."

Maguire holds the same views, for he says that "cyclic albuminuria was not of uncommon occurrence in people with low arterial tension. Albuminuria was common itself in young people who felt 'slack,' with a pulse of low tension. In such cases it seemed to be due to vascular stasis caused by a weak and failing heart." "This variety," he said, "was not of bad prognosis."

Goodheart reported thirty-nine cases of albuminuria without obvious disease which came under his observation. After reporting a particular case, that of a young man in whom it had existed for a number of years, and all that time he appeared in perfect health, he said: "I do not pretend to explain such cases, but they cannot be said to be due to nephritis. The curious intermission in the output of albumin, the suddenness with which it will come and go, is such that one may well find a difficulty

[1] Read before the Association of Life Insurance Medical Directors, in New York, May 29, 1891.

in attributing it to local conditions and least of all to anything inflammatory, for no inflammation, *per se*, could explain it." Its production may be due, he says, to the following causes, viz.: "Congestion of the viscera, overconcentration of urine, oxaluria, hæmoglobinuria, the admixture of albuminous products in the lower passages after the urine has passed the secreting structures, and neurotic conditions."

Sir William Roberts mentions oxaluria as an undoubted cause. Moxon and Collins attributed it largely to morbid matters in the urine, particularly oxalate of lime.

Semmola thinks it is caused by the presence in the blood of albumins of greater diffusibility than the normal blood albumin.

Senator believes there are two sources of it, one being in the blood of the capillaries of the glomeruli, and the other source in the capsule of Bowman down to that of the urethra. He holds to the view that the throwing off and disintegration of the epithelium of the urinary tract adds to the albumin of the normal urine. He also says there are many reasons for believing that albumin is transuded from the blood of the glomeruli into the urine. If this be true, he says, then it is plausible to accept the view that this transudation, like all other transudations in the body, is an albuminous fluid, and that it becomes a part of the urine and is not absorbed. This is probably the chief source, he says, of the albumin in the vast majority of the cases of "physiological albuminuria," and would naturally depend upon the quality of the blood, as well as the pressure and rapidity of the flow of the blood through the capillaries of the glomeruli.

While some of the above causes are exceptional in their character, and others but temporary in their action, the greater number are, as Senator has recently said, influences which, single or combined, act on the majority of mankind with regular changes within every twenty-four hours, hence the albuminuria dependent upon them may appear or disappear with marked regularity within the same period.

Diagnosis of Functional Albuminuria.—In our consideration of functional albuminuria it will simplify the discussion if we exclude all cases of persistent, continuous albuminuria, and all cases of albuminuria associated with any apparent disorder of the kidneys, and confine ourselves strictly to such cases of albuminuria as are not associated with any distinct evidence of disordered health.

Probably no writer or teacher has a more extensive experience with certain forms of functional albuminuria than Pavy; certainly no name is better known in this department of medicine. Since grouping and describing them under the head of "cyclic albuminuria" they have been freely and widely discussed in the profession. To use his language, "they are admittedly cases of functional albuminuria, with a sharply defined and readily noticeable character which groups them together with an easily recognizable class, standing in a distinct position by themselves. Functional albuminuria is the 'generic,' and cyclic albuminuria a 'specific' group contained within it. The distinguishing character belonging to the case is that without evidence from other sources of the existence or pre-existence of renal disease, albumin, under the ordinary course of daily life, is at one period of the day present and at another absent, and that this recurs day after day in exactly the same order. At the period of rising in the morning there is no albumin to be discovered. In an hour or two's time albumin shows itself in increasing quantity for a while, and then, as the day advances, declines and becomes usually entirely lost before bedtime. This condition may run on, with its repeated diurnal variation, not only for weeks or months, but also, it can be said, for years, without anything further becoming noticeable." Pavy here gives the profession in unequivocal terms, a clean-cut description of the distinguishing characteristics of that form of functional albuminuria to which he has given the name of "cyclic."

Senator says "physiological" or functional albuminuria must not contain more than four or five grammes of albumin to one thousand grammes of urine (one twenty-fifth to one twentieth per cent). It must be normal in quantity, specific gravity, appearance, composition, and especially must it be free of morphotic elements.

Tyson, Harley, and others call attention to the fact that albuminuria is less significant when the specific gravity is high. Tyson says when the specific gravity is above 1.020, the assumption is that the albuminuria is functional.

Huebner recently reported fifty-six cases of cyclic albuminuria in Schmidt's "Jahrbücher," and he formulates the following conclusions concerning them, viz.:

1. Cyclic albuminuria is a peculiar and especial form of persistent secretion of albumin by the kidneys. 2. It is not dependent upon a disease of the tissues of the kidneys. 3. It is peculiar to a certain period of development of the organism. 4. It is provoked by a change from the horizontal to the upright position, then lasting a longer or shorter time, to disappear even with the upright position the same day. 5. It is merely an expression of a general weak state of the organism, which at the present cannot be more clearly explained. 6. Its prognosis is good, provided the patients receive proper attention.

Sir William Roberts describes albuminuria in the apparently healthy as follows: "The albumin is usually small in quantity. Its occurrence is intermittent. It is generally absent in the morning urine, after the resting and fasting of the night, and present in the urine of the day. It comes and goes on successive days. As a rule the urine contains no deposit of urinary derivatives, but sometimes a few hyaline casts are discovered (Moxon and Fürbürger). In other respects it is perfectly normal. There is never any dropsy or other collateral sign of Bright's disease."

Tyson says a consideration which goes toward establishing the functional character of it, although not essential to this end, is the absence of albumin on rising in the morning.

Janeway says a distinguishing characteristic is its presence in daytime and absence at night.

Ralfe observed that in functional albuminuria the correspondence between the fluid ingested and that passed out of the body follows the ordinary physiological law.

Significance of Tube-casts.—A number of the prominent writers on functional albuminuria regard the presence of tube-casts in the urine as indicative of structural disease of the kidneys. On the other hand, there are writers equally eminent who hold that the presence of a few casts—particularly the hyaline—are not indicative of organic renal disease.

Johnson, in referring to Tyson's statement concerning the gravity of tube casts, says: "I venture the remark that small hyaline and epithelial casts are often present in the albuminous urine of patients whose speedy recovery may be confidently predicted."

Edes says: "A few casts may accompany a very slight amount of albumin and have no meaning."

Janeway mentions a man whose urine contained casts after boxing; at other times his urine failed to show casts. From this, he said, "it follows that hyaline casts may appear in the urine, quickly formed and as quickly disappear."

Weston's urine, after an extraordinary feat of pedestrianism, showed the presence of casts both hyaline and granular, which vanished as quickly as they came, after a night's rest.

Saundby, referring to "transient albuminuria" in healthy persons, said: "In one or two cases there were a few oxalates, and in one or two a few hyaline casts; but the latter were quite exceptional, and, as we know, they are of no pathological significance."

Roberts says: "As a rule the urine contains no deposit of urinary derivatives, but sometimes a few hyaline casts are discovered;" and he quotes Moxon and Fürbürger in support of this position.

Lambert, Medical Officer of the Equitable Life Assurance Society, writes me: "I am convinced that the presence of an occasional cast does not necessarily imply destructive or permanent disease of the kidney."

Grainger Stewart observed, in what he calls "paroxysmal albuminuria," sudden and copious occurrence of albumin in the urine with numerous casts, the process lasting only a short time, and recurring at intervals, and he has never known them to prove permanently injurious.

Bartels mentions a case where, besides the albumin and other sediment, there was epithelium and a quantity of thick hyaline casts in which were clustered the ordinary well-conditioned epithelial cells from renal tubes, and after the third day no further casts could be discovered.

Allchin says: "Casts afford practical information rarely, if ever, conclusive when taken alone. The fact that casts are abundant in any sample of urine is not in itself of necessity a serious sign."

Harley regards the specific gravity of the urine of much more significance than the quantity of albumin or tube-casts.

Prognosis.—No one now questions the fact that albuminuria may occur, and, as a matter of fact, does occur frequently in persons otherwise apparently healthy, and it is admitted that this albuminuria may continue for years without any apparent impairment of health, but the question on which the profession is not a unit is: What will be the ultimate result of this albuminuria? Will it continue simple or will it terminate in structural disease of the kidneys? These questions are involved in the discussion of the prognosis of functional albuminuria, and are questions of vital importance to us as physicians and as medical officers of life insurance companies.

George Johnson has known of cases of "intermittent albuminuria" to make a good and final recovery after one, two, three, five, and seven years' duration. He also gives the history of a case which persisted for thirty years before a fatal termination. Then he says, as regards the prognosis of this class of cases, "the absence of albumin at any period of the twenty-four hours, the urine being of normal color, quantity, and specific gravity, and free from tube-casts, warrants the conclusion that there is no serious structural change in the kidney, and justifies a hopeful prognosis."

Grainger Stewart said: "So considerable a proportion of my cases have gone on for long periods without having terminated in structural disease, that I am confident that it must be rare when they have such an ending," and he states that he gives a hopeful prognosis if the quantity of urea is normal, the pulse and heart in a healthy condition, and there is an absence of tube-casts.

Professor Saundby says that "during the last ten years I have seen scores of cases of functional albuminuria and I have not heard one of them developing into Bright's disease; many of them are known to be quite well."

A recent leading editorial in the *British Medical Journal*, commenting on the ultimate results of this form of albuminuria, says we may have to wait another generation before this question can be finally set at rest. "It may, however, be taken as certain that the albuminuria does not pass into Bright's disease."

Edes says: "Some cases of this kind have been followed for years without the occurrence of any symptoms leading to a suspicion of progressive renal disease. In many the albumin has disappeared without special treatment and without the change being assignable to any particular cause."

Mahomed says: "For my part, I am quite convinced that we may have albuminuria with practically healthy kidneys."

Klemperer says: "Cyclic albuminuria exhibits no signs of Bright's disease. Indeed, all symptoms, except albuminuria, may be absent. Its course is chronic; it is the source of no danger to life; it does not become transformed into serious disease of kidney; and it may finally greatly diminish or disappear entirely."

George Harley says "that a quarter of a century's experience in the treatment of the various kinds of albuminuria had taught him that the specific gravity of the urine was a far more reliable guide to prognosis than either the quantity of the albumin or tube-casts." Albuminuria unassociated with renal structural derangements, he said, did not cause the twenty-four hours' urine, as a rule, to fall below 1.015 of specific gravity, and could thus be distinguished—other things being equal—from the incurable albuminuria of Bright's disease.

Huebner Schmidt's "Jahrbucher," 1890, says the prognosis is good, provided the patients receive proper attention.

Pavy says, where traces of albumin only are observed, without any other indications of renal disease, the prognosis is favorable. When there are cases in which a notable amount of albumin is found at one period of the twenty-four hours and none at the other periods, and no other symptom of renal disease, the prognosis is favorable.

Sir William Robert says: "The prognosis in functional albuminuria is favorable. It is now certain that a sensible albuminuria is of much commoner occurrence in healthy persons than has been hitherto supposed."

Senator holds that normal urine may contain albumin, and consequently that no unfavorable outlook attaches to the presence of "transitory or paroxysmal" albuminuria.

Albuminuria and Life Assurance.—We are now brought face to face with a very difficult problem. Thus far we have spoken as physicians who have been intently engaged in investigating and considering a symptom of a grave disorder, which, until recently, has been accepted as proof positive of the presence of the dread disease. Our desires and interests have been enlisted in the hope that the significance hitherto attached to that symptom may be removed, and from the evidence adduced we have felt warranted in giving our patients a hopeful prognosis. Now, however, we assume our official relation as the advisers of the great business organizations which have retained us to act in their interest. In our former attitude it was not only allowable, but it was our duty to take the most hopeful view of the situation; now, however, there are pecuniary interests involved in our opinion, and we must be guarded in its expression. Pavy aptly states the case as follows: "It may be taken as standing in the position of a border line, with a favorable outlook on the one side and a serious one on the other, and everything depends upon whether, by the light of other considerations, it is viewed rightly or not."

The question of the insurability of persons having albuminuria in any form, is one that has attracted a great deal of attention in recent years, and it has been, and is still being discussed by medical men and medical organizations, the world over, with an ever-increasing interest. As the chief medical officers of life insurance companies we are more interested in the subject than any other class of medical men, and it behooves us to keep ourselves thoroughly informed on every stage of the discussion.

At the fifty seventh annual meting of the British Medical Association, in 1889, a discussion "On the Prognosis of Albuminuria with Special Reference to Life Assurance," took place, which was replete with interest. Fifteen distinguished physicians took part. One-third of them favored accepting persons with albuminuria, who were otherwise apparently healthy, at advanced rates or for short terms; another third favored postponement until the disappearance of the albumin, and only two gentlemen were for outright rejection. The fact was recognized that a number of agencies might produce temporary albuminuria, which was of no significance whatever; and when there were but slight traces of albumin, with no other symptom of structural or other disease, the case was not considered invalidated. Persistent albuminuria, however, was regarded as significant of renal dis-

ease. Pavy said: "I do not consider that medical knowledge is at present in a position to enable us to differentiate these cases from those which may become developed into well-marked Bright's disease. Concerning "paroxysmal," "intermittent" or "cyclical" albuminuria, a goodly number were of the opinion that it did not end in structural disease of the kidneys. Pavy said that a favorable opinion of the future of this group may be given; and he thought that it will be safe for assurance companies to admit them as eligible for acceptance, but with an additional premium to meet the possible contingencies.

Johnson favored their acceptance at an advanced premium.

Saundby is a firm believer in the innocent character of albuminuria in certain cases, and would gladly see some changes in the present practice of the majority of assurance companies, and he said that one of the practical results of the study of the incidence of albuminuria in the sick and the healthy will be that the assurance companies should relax their hard-and-fast rule of rejecting or deferring all applicants whose urine contains albumin. "I know one otherwise perfectly healthy man," he says, "who was rejected by an assurance office twenty years ago for albuminuria, and whom I had to refuse for the same cause a year or two ago;" and he adds, "I have had to postpone dozens of applications of young men with albuminuria lasting for years." "These cases," he said, "might very well be insured for five years, with the condition that at the end of that time they should submit themselves for re-examination, when the company would have the opportunity of deciding finally whether to take the life or not."

Tyson, in discussing "The Relation of Albuminuria to Life Assurance," calls attention to the fact that whenever, in addition to the absence of all other symptoms of renal disease, the "real" specific gravity—that is, the specific gravity of the twenty-four hours' urine—is above 1.020, "another most important fact is in evidence against the presence of organic disease and in favor of the view that the albuminuria is functional." This is in harmony with the opinion held by Harley, who after a quarter of a century's study of renal disease, attaches more significance to the specific gravity of the urine than to the presence of albumin or casts.

Tyson concludes by saying "that life assurance associations should recognize a condition of functional albuminuria out of consideration of their own interest, as well as in justice to a class which is coming to be recognized as more numerous as our knowledge increases, and who are blindly excluded from benefits to which they are entitled." In a recent note to me he says, "I am confident that certain cases of albuminuria are insurable if they can but be selected."

Grainger Stewart says: "The existence of albuminuria is not of itself a sufficient ground for rejection of a proposal for life assurance."

Goodheart lays down the following as a good rule of practice: If a case presents itself for examination, and albumin is found in the urine, it is a case for further examination; if it be a young person, and the examination be conducted upon the urine of the early morning, the albumin will probably have disappeared at the next examination, or within a very short time, and it is a condition of no importance. If the albumin is in any quantity, and its presence is persistent or reappearance frequent, it must be regarded as a grave symptom to be watched.

Rabagliata said that the Scottish Widows' Fund, with which he is associated as its medical officer, recently found that the average age at death of persons with albuminuria was fifty-seven years. He therefore proposed that where only a trace of albumin was present, and no casts, and with no other definite lesion, the life might be received as one having an expectation of attaining its fifty-seventh year. This would mean rating up moderately lives under forty years in which albumin was present, and rejecting those absolutely which were over forty or forty-five years of age.

Pollock, in his "Medical Handbook of Life Assurance," lays down this rule: "Albuminuria presently existing, and known to have existed for years, in persons of otherwise perfect health and good family history, may be assured for a short period of say five years, with an addition to the premium, and come up again for examination at the end of that period."

The medical officer of The Provident Life Assurance Society of London writes me that he exceptionally accepts of cases of albuminuria, but as "under average lives," provided there is clear evidence of periodicity (1) as to absence of albumin at some period, and (2) of varying amount of albumin at others; the entire absence of casts in urine, and evidence that the life has never suffered from any disease of the urinary organs or of the vascular system, and that the proposed life is a young subject.

I am fully aware that it has been, and still is, the rule of life assurance companies to decline all cases of albuminuria, not excepting those who present no other indication of impaired health. Nevertheless, we have indubitable evidence from competent observers, the world over, that albuminuria is not at all infrequent among persons apparently healthy; and we have the testimony of many eminent observers and writers that we may have albuminuria with practically healthy kidneys, and that the so-called functional albuminuria does not necessarily end in Bright's disease.

Life assurance companies are organized on a business basis to assure the lives of all assurable persons. These companies look to us as their chief medical officers to inform them who are assurable. If the conclusions toward which the investigations of leading observers and students of albuminuria are now pointing are correct, then our attitude on the subject is wrong, and we are doing injustice to a large class of people by excluding them from the benefits of assurance, and besides, we are doing the companies an injustice by depriving them of a revenue which they might otherwise receive from this class.

We have learned that albuminuria is much more common among presumably healthy people than was formerly supposed to be, and Professor Grainger Stewart makes the broad statement that tests have demonstrated its presence in nearly one-third of the population at large.

It is only in recent years that assurance companies have required a urinalysis of any of its candidates for assurance. Even now only fifty per cent. of the companies require it of all candidates, and one-half of that number have only required it for the past five years. The remaining fifty per cent. only require it when the candidate is forty-five years of age or over, or when the amount applied for is $5,000 or over. It is safe to assume that one-half of the persons assured during the past eight or ten years did not have an examination of their urine made, and practically all who were assured before that period were not subjected to a urinal examination. Now, if albuminuria among persons apparently healthy is but the forerunner of renal disease, and if one-third of the population has albuminuria, we will be justified in expecting a heavy mortality from Bright's disease among the assured, particularly among those who were assured without a urinal examination. As a matter of fact, the mortality from Bright's disease among American companies for the past five years has been but 5.66 per cent. Hence it is evident that Bright's disease does not account for but a fraction of the cases of albuminuria met with.

Grainger Stewart said that it did not account for one-half the cases of albuminuria met with in practice. A recent investigation by the medical officers of one of the

[1] Some of the companies included deaths from all kidney diseases in their report.

largest companies represented in our association shows that Bright's disease does not account for more than 17 per cent. of the cases of albuminuria met with at the home office. The records of the declensions of those examined at the home office of this company, for the presence of albumin in the urine, during the years 1877, 1878, and 1879, and for January, 1880, show the total rejections to have been 137 persons; and of that number 57 have died; 11.6 per cent. of the deaths were from Bright's disease, and 5.84 per cent. were from heart disease. Crediting all of these to Bright's disease and we have at the utmost but 16.90 per cent. It may be said that the returns are not all in from this class, but of those which are in, 24.70 per cent. of them died from causes which have no relation to structural disease of the kidneys.

It is true that scarce fifteen years have elapsed since the attention of the profession has been called to the circumstance that albumin may be found in the urine of persons who do not exhibit any of the general symptoms of Bright's disease, nor even any deterioration of health; but it is also true that the evidence of those fifteen years goes far to prove that these cases of albuminuria do not all end in organic disease of the kidneys. With the information which these years have given us, and from a careful study of the testimony of the most trustworthy authorities on the subject, I think we will be warranted in accepting the following rules for our guidance in the consideration of candidates for life assurance having albuminuria, viz.:

General Rules.—1. There should be nothing in the family history indicative of heredity of Bright's disease, and there should be no symptom of renal disease in the personal history except albuminuria.

2. The candidate should be under forty years of age, in good health, and there should be no history of gout, rheumatism, syphilis, lead poisoning, nephritis, intemperance, chronic dyspepsia, or dropsy.

3. There should be no indication of hypertrophy of heart or increased arterial tension, no accentuation of the aortic second sound, and no palpitation or dyspnœa.

4. There should be no retinal changes.

5. The color, density, and quantity of the twenty-four hours' urine should be normal, or it may be darker in color and heavier in density.

6. The specific gravity of the twenty-four hours' urine should not be below 1.020. It may range from 1.015 to 1.030.

7. The precipitated albumin should not exceed one-eighth of the urine.

8. There should be a period of the twenty-four hours when the urine is free from albumin.

9. The urine, as a rule, should contain no tube-casts. When, however, the specific gravity and quantity of urine are normal, the presence of a few hyaline casts have no serious import.

When the above conditions have been met, and we are convinced of the ability of the medical examiner, and are satisfied with the completeness and carefulness with which the investigation of the case has been made, I think we can safely approve the candidate for a short endowment policy.

To a person who has passed the above gauntlet and been subjected to a rigid medical examination, this action will doubtless appear illiberal, but until the clinical significance of albuminuria in persons apparently healthy has been finally determined by observations upon one full generation, we cannot, and probably ought not, to expect life assurance companies to do any better for them.

Vomiting of Pregnancy.—Dr. Graily Hewitt has recently published a work on this subject, in which he reiterates his frequently-expressed views as to the causation of this distressing symptom. He endorses the opinion of many authorities that the vomiting is a reflex act which starts from the neighborhood of the internal os, and he claims that the irritation arises from malposition of the uterus, causing compression at this part, and his treatment therefore consists chiefly in reposition of the displaced organ.

NASO-PHARYNGEAL CATARRH A CAUSATIVE FACTOR IN GASTRIC CATARRH.[1]

By LOUIS FISCHER, M.D.,

ATTENDING PHYSICIAN TO THE CHILDREN'S DEPARTMENT OF THE GERMAN POLI-KLINIK, NEW YORK.

Mr. Chairman and Gentlemen: It is my object to direct your attention to the frequency with which we find the association of catarrhal pharyngitis and catarrhal gastritis in adults and children. Moreover, I have observed that catarrhal gastritis is the direct result of the existing pharyngitis, and have also verified this observation by directing the treatment to the cause, *i.e.*, the pharyngitis, and thus removing the effect, namely the gastritis.

My first observations were made about four years ago, at which time I suffered with an attack of acute catarrhal pharyngitis, and further observations of patients whom I then attended revealed the same condition of affairs. An abundance of opportunity for observing the co-existence of the two diseases were given me in the large amount of material at my disposition at the Children's Department of the German Poliklinik of this City.

Freudenthal's Observation on my Own Case.—Freudenthal, while attending to the catarrhal pharyngitis with which I suffered, observed the same as I shall this evening describe, and an attack of subsequent gastritis, which always developed secondarily, immediately subsided when an astringent application was made to the pharyngeal catarrh.

Anatomical Relationship.—When we consider the anatomical position of the pharynx, situated above and the stomach below, it is easy to understand how all exudations from the pharynx, be they mucous, muco-purulent, muco-sanguinolent, or otherwise combined, can and usually do gravitate toward the stomach, either by involuntary or voluntary deglutition, especially at night, in the same manner as the insensible swallowing of saliva is continually carried on.

Children show the picture remarkably. They cannot hawk and spit as adults, consequently all catarrhal exudations forming or lying in the pharynx, and interfering with the natural comforts of the child, tend to produce, through irritation, swallowing movements, and thus it is that large quantities of septic material are forced directly into the stomach, in this way causing an infection. In several children where stomach washing was resorted to large quantities of catarrhal (usually muco-purulent) exudation was found, corresponding with the increase or decrease of existing catarrhal pharyngitis.

Unconscious Relief by Deglutition.—As near as I could determine, I found children rarely expectorate under two and a half years of age. I found nothing on this point, although I searched a considerable amount of literature. According to J. Solis-Cohen ("Pepper's System of Medicine") pharyngeal catarrhs are more frequent in the young. It is easy to understand, therefore, how pharyngeal catarrhs, be they superficial or be they in the submucous structures, including at times the sheaths of muscles or progressing to suppuration, and extending along the subpharyngeal connective tissue, discharging pus by spontaneous rupture, and emptying in the stomach, can and do irritate the mucous membrane of the stomach, and thus be the direct cause of gastric catarrh.

Probable Excoriation.—Sexton, in the Medical Record, January 30, 1886, says: "Catarrh exuding from conjunctival mucous membrane and from anterior nares excoriates cheek and lips, and sometimes produces an eczematous eruption at the seat of irritation."

Post-mortem Examinations.—As neither of the diseases in question—gastritis or pharyngitis—are fatal, and post-mortem examinations are very rare, we have very little doubt but that the discharges from the posterior nares and pharynx can irritate a healthy mucous membrane and excoriate it, as it can on a healthy skin situated outside of the body. This may, however, not be the case.

[1] Read before the Section of Pædiatrics of the New York Academy of Medicine, May 14, 1891.

Microscopical examination of several catarrhal exudations found in the stomach, as also comparative examinations of exudations in the pharynx, were made by me, but nothing definite has as yet been ascertained.

Ewald's Method.—Ewald's method of extraction of gastric fluids, and subsequent examination for presence of acid, by means of the phloroglucin-vanillin test, was the one resorted to by me.

Chemical Reaction of Catarrhal Exudations.—One point worth mentioning is the reaction of mucus, which is alkaline; so is the reaction of pus also alkaline. It is possible that the neutralization of the gastric secretions, which are acid, may also explain the cause of the indigestion and catarrh.

A. Jacobi on Diseases of Mucous Membrane.—A. Jacobi, in his book on "Intestinal Diseases of Infancy and Childhood," pp. 120, 121, says: "Diseases of mucous membranes are apt to extend over large surfaces; besides, the lymphatic apparatus participates in every process affecting the mucous membrane. Diseases of the stomach and intestines are frequently found together, diseases of stomach will extend downward, and diseases of the intestines upward according to this. Is it not possible that the lymphatics are directly responsible for the co-existence of both the catarrhal affections?"

Pathology of Gastritis.—Wilson Fox, in "Pathology of Gastritis," in "Reynolds's System of Medicine," cites Beaumont's observations and says: "There are also seen at times aphthous crusts; abrasions of the lining membrane like the rolling up of the mucous coat into small shreds and strings, leaving the papillæ bare for an indefinite space, is not an uncommon appearance. The gastric fluids extracted were mixed with a large proportion of thick, ropy mucus, and considerable muco-purulent matter resembling the discharge from the bowels in some cases of chronic dysentery. It is, however, difficult to exactly describe the lesion, as rarely has a typical case been examined post-mortem."

Gruenhagen's "Physiology," Band III.—One point worth considering here is described in detail by Gruenhagen, "Physiology," Band III., which he terms "Das Bedürfniss des Nachschluckens," and which is proved by a desire to swallow after we have already swallowed fluids, and is caused by the peripheral distribution of the laryngeus superior nerve, by which means very easily large masses of accumulated catarrhal fluid are forced into the œsophagus and stomach.

One of the strongest arguments in favor of proving that gastritis is caused very frequently by the existing and consequent swallowing of catarrhal exudations of an acute pharyngitis is proved by the fact that by attending and curing the pharyngitis, the gastritis ceases, as was observed by me in numerous instances; in other words, I frequently found pharyngitis and gastritis stand in the same relation as cause and effect.

40 Rivington Street.

RECENT CASES IN THE COURTS.

By HENRY A. RILEY, Esq.,

NEW YORK.

Smells and Injunctions.—It is sometimes said that medical men when called as experts are more apt to have different views on points connected with their profession than to agree, but any frequenter of the courts is familiar with the absolutely contradictory evidence which is given by apparently reputable witnesses in almost every case that is tried.

A case involving health legislation and the right of a court to stop the manufactory of paint came up recently, and the following *résumé* of the evidence was made by the court: "These odors were described by witnesses as 'the smell of paint,' 'paint smell,' 'heavy,' 'the smell of varnish,' 'resinous smell,' and 'piny.' Residents in the vicinity of the works testified that during the time men-

tioned in the complaint, they had been constantly annoyed by odors, smoke, and soot, which came from the works and entered their houses, producing, as they testified, headache, nausea, vomiting, and other pains and aches injurious to health; that in warm weather to keep out the soot and smoke they were compelled, to their great discomfort, to close their doors and windows; that smoke settled on their furniture and on their clothes which had been washed and hung, and which they were obliged to wash again; and in some instances tainted their food. On behalf of the defendants testimony was introduced tending to show that nothing of an unhealthful or injurious character emanated from the factory, and that the only 'paint smell' there could be was simply the smell caused by boiling linseed oil, about once a week, in the manufacture of varnish; that no smells emanated from the other parts of the factory at all, and could not; that the men, women, and girls in the factory were in excellent health, and had never been ill from being there; that one witness, a member of the committee to investigate the business in question, had visited the place thirty-one times before he could detect an unpleasant odor, and that in warm weather; and that there was nothing unwholesome or injurious to health about the business."

The trial court held that the facts were substantially as claimed by the plaintiffs, and the defendants were convicted. The appellate court said that the facts having been found by the court below in a certain way this could not be changed, and that the plaintiffs were entitled to an injunction against continuing the business. It was strongly intimated, however, that the injunction was an unnecessarily hard remedy to apply to the case.

Astrology, Christian Science, and the Law.—The astrologer and the Christian scientist both seem to be about on a par as to their contempt for the ordinary practice of medicine, although the methods employed by these two rival schools of quackery are absolutely different. Both of them are, however, likely to run foul of the courts if a sick person is left entirely unprovided for, except by incantations or prayers, and death ensues from the mere neglect.

Not long since in Brockport, Mass., a woman poisoned herself and her three children with a drug indicated to be used by the mummery of an astrologer. The woman and one child died, while the other children were reported to be recovering. The astrologer was arrested and placed in jail, but no statement has yet been noticed of any other proceedings in the case. It is to be hoped that the prosecution will not be dropped.

Some Curious Legal Nuisances.—The following are some of the alleged nuisances for which injunctions and damages have been asked from sympathetic courts and juries. In a recent English case an enthusiastic amateur played daily eight hours on a violoncello, and on Sundays a little longer sometimes. To add to the misery caused, the player lived in a flat. The judge before whom the case came decided that three hours was long enough for any human being to play on a violoncello, and the injunction issued.

In a case before the Court of Common Pleas, some time ago, in New York, a person was brought up for trundling in a carriage overhead his teething baby, both by night and day. The judge, who must have been a married man, held that the noise was not unreasonable, and refused to interfere.

In another English case a chime of bells at Deptford was not allowed to ring because the noise was offensive to the majority of the property-owners in the vicinity.

The newspapers recently mentioned the sad case of a discharged chorister who took a horrible revenge on the congregation by sitting in a pew and purposely singing out of tune. Whether he was indicted or not for disturbing public worship does not appear.

There are few annoying sounds which have not, sooner or later, been alleged as nuisances, but the courts hold that many of them must be endured.

Practically no Death Penalty in New York.—The Supreme Court of the United States has recently dismissed the appeals taken from the New York State courts in the cases of two condemned murderers, and has intimated that such appeals ought not to be allowed for purely technical and frivolous reasons, and with the only object of gaining delay. It is difficult to see, however, what is to prevent unscrupulous attorneys from taking successive appeals under the present law, and it may be that there will be no remedy until Congress passes a law regulating with more care the whole matter of appeals in criminal cases from State tribunals.

The present condition of affairs is in the meantime rather appalling. There are now six murderers in Sing Sing under death sentence, and yet there is no legal warrant for their execution, and apparently can be none for some time to come. In addition, there are twenty-five men in the Tombs in this city awaiting trial for murder, and with the present outlook they all have several years of life to enjoy without let or hindrance.

A State Medical Library.—Governor Hill has just signed the bill passed at the last session of the Legislature providing for the acceptance by the State of the Albany Medical College Library, which will form a nucleus for a State Medical Library. Five thousand dollars is appropriated for the care of the library.

Oleomargarine.—The law in regard to the sale of oleomargarine in this State seems quite well enforced, and the complaints by the farmers of interference with their dairy interests are not often heard. Nevertheless few persons who visit grocery or butter stores will ever see any packages labelled "oleomargarine," as required by the act.

A recent English case turned on the question whether the package containing the imitation or adulterated butter was "exposed to sale," and the court held that "exposed for sale" meant that the package should be in sight of the purchaser with the label attached.

It appeared that the package was placed, in the ordinary course of business, and without the intention of evading the law, behind a screen out of view of the purchaser.

This was held to be a violation of the law, even if not intended as such.

Removal of the Dead.—The removal of the bodies of the dead from old burying-grounds to new ones is often the occasion of bitter legal quarrels, and yet the courts almost always hold that such removal can be made when a proper cause is shown.

A case of the kind which may not get into the courts, is noted in a recent law passed by the last New York Legislature authorizing the Board of Education of this city to remove the bodies in the old cemetery between First and Second Streets and First and Second Avennes, and reinter them elsewhere. The site is to be used for a new school building.

HYSTERIA IN THE MALE.

By J. D. KELLY, A.M., M.D.,

LOWVILLE, N. Y.

The variety of well-marked hysteria in a male will render a somewhat detailed account of the following case and of its treatment of interest, and of possible value to the profession.

The patient, a young unmarried man, twenty-six years of age, had heretofore never been seriously sick, and beyond noticeable nervousness, had enjoyed undisturbed health. Last November, without noticeable cause, he began to complain of some trouble with his throat. He made frequent and repeated efforts to cough or hawk up, as if accumulated mucus, without apparently accomplishing anything. These efforts at clearing his throat became more and more frequent and distressing as days went by, and gradually his family noticed he was becom-

ing depressed and despondent. He remained indoors constantly, and fled to his room upon the entrance or even the approach of any person to the house. About the middle of December he began to remain in bed, declaring that he was not able to get up nor to sit up. His nervousness and despondency became more marked, and his fear of any stranger entering his room pitiable. However, upon taking to his bed a physician was called, who, after a few weeks of ineffectual treatment, was succeeded by another. About February 1st I saw the patient, who was still in bed, presenting the following conditions: Face pale, countenance expressing fear, and covered with clammy perspiration. Pulse 120, and small; temperature normal. Tongue moderately coated, yellowish-brown at base. Eyes bright, pupils somewhat dilated. Appetite good, patient taking three full meals daily from the first. Bowels constipated, no movement in the preceding ten days. Urine scant and high-colored; phosphates in abundance. Sleep disturbed by unpleasant dreams, and not sufficiently restful. His mother told me that he was daily becoming more nervous, that he required her constantly in the room, and at first permitted her to sew, and read often to him aloud, but latterly he would not allow her either to read or do any kind of work whatever, requiring her to sit by him in quiet silence. When necessary to leave him for only a short time, he invariably declared that he would be dead when she returned. He was constantly bathed in perspiration, feet and hands cold, and at time of my visit the nails and skin of his hands and feet were livid. He made almost incessant efforts to clear his throat, frequently raising his hand to his neck as if expecting to discover some abnormality there. To my question as to how he felt, he replied: "Pretty well, only for my throat." I then asked him, if that was all, why he stayed in bed? He replied: "I am too weak to sit up." I then examined his throat, and beyond indications of chronic catarrh and considerable hyperæmia of the mucosa from the constant irritation, discovered nothing. He appeared to be disappointed at this announcement. I asked him to describe just what the trouble was as he felt it in his throat. He said that there seemed to be something there that he wanted to dislodge or get up, but that he never could, no matter how often or how hard he tried. He said at times it was much worse, there was a feeling as if a ball was lodged in his throat, and at times as if something was choking him. His mother added that in those paroxysms it often seemed as if he would not live ten minutes. In his mother's absence I sought in vain for some history of excess, self-abuse, or seminal loss. He declared there was nothing wrong about him except his throat, and both he and his mother entreated me to do something to relieve that, assuring me that if his throat was well he would be "all right."

In the way of treatment I first prescribed comp. cath. pil. to unload the bowels, and followed that with pil. podoph. and hydrang. cum creta till there were indications of free hepatic function. I then put him upon pot. brom. and sod. brom., gr. x. āā, t.i.d. He appeared somewhat improved at the end of the first two weeks. I then told him that he must leave his bed every day at an early hour, and, after sponging the body over quickly with cold water, rub the skin briskly with a coarse towel. I also prescribed sherry wine, concealed under fl. extr. sars. camp., t.i.d., and directed him to dress and sit up daily and to recline upon the lounge only when tired. At the end of the next two weeks he had so improved as to go out-doors a few times and to visit me at my office. However, he still complained of the difficulty in his throat, and labored quite as incessantly at clearing it. I saw that while much of what we had gained was due to regulating the functions of his liver and bowels, a great deal more was owing to the moral force of much that I said to him in the way of assurance and direction. Having meantime increased the doses of bromides, adding trs. hyosciami and belladonna, and observing only slight decrease of throat symptoms followed by gradual reappearance of all their distressing features, I suspended all medication, and on March 10th hypnotized the patient at my office, and while profoundly in that state suggested to him that there was nothing the matter with his throat, that he must not hawk, cough, nor make further effort to clear his throat because there was nothing in it. At the end of fifteen minutes I dehypnotized him. He appeared to be dazed for a few minutes, but upon recovering himself he said that he did not hear one word of what I said to him. I noticed, while he remained in the office, that there was a total absence of any effort at coughing or hawking. The next day his mother called and said that the contrast in his conduct with his throat was wonderfully marked; that, whereas the day before I hypnotized him he hawked, hemmed, and cleared his throat every few seconds continually, on the day following she did not notice him do so above three or four times all day. She said that he still complained of pain in his throat, and I told her to ask him to come to the office on the following day. He did so, and on this second occasion I hypnotized him again, putting him profoundly asleep in just six minutes. I then reiterated what I had suggested on the preceding occasion, and added, what I had before omitted, the suggestion that he would not feel pain any more in his throat. I allowed him to sleep thirty minutes, and, during that time, in order to demonstrate how profound was his hypnotized state, I pricked the skin of his face with a pin at several sensitive points without evoking the slightest flinching, and finally I thrust the pin through the pinna of his left ear without observing the faintest movement indicating pain on his face, although I closely watched for it. He complained, upon awakening, of numbness in his arms and legs, and for some minutes rubbed them as if to restore sensation. He could recall nothing of what I had said to him, and made no allusion to the pin-pricks nor to the transfixion of his ear.

When seen again, a few days later, I was told that he had not mentioned pain in his throat since the last hypnotization, nor had there been any return to efforts at hawking or clearing it. He appeared to be greatly improved, slept well and throughout the night, awaking refreshed in the morning. He was henceforward brighter, more cheerful and hopeful, went out every day and enjoyed the society of others. He is now engaged at work and appears to be entirely relieved of all his former distressing symptoms. He has taken no medicine since I first hypnotized him.

TREATMENT OF WHOOPING-COUGH BY ATOMIZATION.

By H. ERNEST SCHMID, M.D.,

WHITE PLAINS, N. Y.

When I propose to say a word regarding the treatment of this dreaded disease, I do so because the method pursued by me has been productive of better results in my hands than anything else on record. The drugs used are not new, to be sure, but I do not know of an instance where they have been employed in this my combination of them. I rely entirely, no matter what stage of the disease, on spraying my patients with a solution of carbolic acid, menthol, cocaine, glycerine, and cherry-laurel water, generally in some such proportion:

℞.	Acid carbolic	grs. vj.
	Menthol, four per cent. solution	ʒ iv.
	Cocaine, three per cent. solution	ʒ iij.
	Glycerine	ʒ j.
	Aquæ laurocerasi	ad ʒ ij.

This I direct to be used by atomizer every three hours —but I mean a thorough use, a brutal one, if necessary. I have the child held forcibly by one or more persons, and disregard any apparent strangling of the little one during a vigorous atomization. The nozzle of the instrument must be directed as far into the mouth of the

patient as possible. During the struggling and sputtering and strangling some deep respirations will ere long be made, and the object is accomplished. At first, of course, in most cases, violent paroxysms of coughing may result from the spraying, especially if much force has to be used with the child, but these soon cease and palpable effects are speedily noticed by the parents. The great point is to be able to impress them with the importance of perseverance.

I have seen the whoop arrested by this means after one thorough spraying, coughing without the whoop still going on for a while, and I have been gratified with inducing perfect recovery in one and in two weeks. A few cases in illustration might not be out of place.

A young lady, while on a visit in New York, was attacked by the cough. An excellent physician attended her, but the violence of her attack was terrible, and only excessive doses of anodynes gave her any rest at all. After two weeks she concluded to return home and arrived here perfectly stupefied, with her eyes starting out of their sockets from the dreadful straining accompanying the whoop. I stopped internal medication at once, put her on my spray, and in one week she was well.

I was called to see two children, one three years, the other not quite a year, old, brought home by their mother from a visit to some distant place, and sick with whooping-cough. Both whooped badly. After the first spraying the baby ceased whooping altogether, and both were entirely well in two weeks.

A gentleman sent for me to consult me about his two-year old boy who had the whooping-cough. The family had come from Europe a short time before on a visit merely, and were booked for their return to France two weeks later on. Mother and child had gone to North Carolina to visit some relatives, and there the latter was taken with the cough. I expressed the belief that the little one might be cured in time for the sailing of the steamer if it were here. The father at once telegraphed the family to come on. It was very hot weather. The little one almost perished on the trip, and I feared he would not live through the first night following his arrival, for bronchitis complicated the pertussis, and a highly febrile condition prevailed. However, he rallied very much by morning and the spraying was then begun. The struggles of the determined little fellow were very great, but the treatment was carried out mercilessly. In consequence of this I ceased my attendance in eight days, and the family sailed for Europe on the day previously appointed, with a perfectly recovered child.

A short time ago I found in one of my families three children sick with pertussis. The two older ones, after considerable persuasion and coaxing, permitted the use of the spray, but the youngest refused it. The two elder ones recovered in two weeks, while the youngest is going through the slow, protracted course of internal treatment, the mother not being willing to use force.

From my repeatedly successful employment of this treatment I feel justified in claiming that it promises to be one of the most efficient methods yet devised, provided it be used intelligently, thoroughly, and, if necessary, energetically.

May 16, 1891.

TWO CASES OF TRICHINOSIS.

By JOHN H. BARRY, M.D.,

HOUSE PHYSICIAN, ST. FRANCIS' HOSPITAL, NEW YORK.

At a time when so many of the rarer diseases seem running rampant in our midst, and the profession consequently is aglow with enthusiasm, it may not be amiss to record two cases invested with unusual interest.

On April 27th, Mrs. J. M——, aged twenty-six, was admitted to St. Francis' Hospital, presumably suffering from a severe attack of epidemic influenza. Her history was that she had been taken with severe colicky pains one week previous to admission, which were soon followed by fairly profuse diarrhœa. The following day brought relief of symptoms and she was able to do her housework in a more or less satisfactory manner for one week subsequently. She was then stricken, however, with severe prostration, her temperature rose to 102° F., and she sought relief at hospital. On attempting to sit her up in bed and examine her lungs, she complained bitterly of intense pain in both thighs.

The visiting physician's (Dr. Siebert's) attention was called to this fact whose immediate impression was that the case was one of trichinosis.

Her husband, aged twenty-nine, was by this time also a patient in the hospital, and gave strictly parallel symptoms to those of his wife's, save that the initial diarrhœa was lacking in his case. The pain, at first referred to thighs, became more and more diffused and was soon followed in both by a pronounced œdema of lower extremities there being a tendency even to gangrene in the woman's left groin.

Mrs. M—— was seemingly tongue-tied, a circumstance doubtless due (in the light of subsequent events) to paralysis of motor nerves and muscles of tongue. This rendered her speech inarticulate and thus it was we had to elicit the better history from the husband, who, as a matter of fact, was less markedly prostrated throughout the course of the disease.

He related the participation of himself and wife in a meal of raw beef and pork on the evening of the wife's colic and diarrhœa.

The temperatures remained about 101° F. or 102°F., until within two days of death, when it registered 99⅘° F. in either case.

The man developed, and recovered from, the typical influenza pneumonia while in hospital.

The woman died May 9th, and an autopsy was performed by Dr. Edmund C. Wendt. Sections of intercostal muscles, of recti muscles, and of deltoid, under the microscope showed the trichinæ in large numbers and some as yet living.

The man died May 11th, and the autopsy revealed a like condition of the muscles under the microscope.

The cases are of interest, 1, because of their rarity; 2, because of an ante-mortem diagnosis having been made; 3, because of the suspicion they awaken of the possibility of other cases running, recognized or unrecognized, among the community.

THE INFLUENCE OF DIRECT ELECTRIZATION UPON GASTRIC SECRETION.

By ALLEN A. JONES, M.D.,

BUFFALO, N. Y.

For a somewhat extended period I have been working with Dr. Charles G. Stockton. On January 1st, of this year, while treating a patient by direct electrization within the stomach, I tested the water withdrawn immediately after the constant current had been applied by means of the Stockton electrode. This water had served as a conductor within the stomach. My test was made for free hydrochloric acid, and I found it present in large amount. As I discovered no acid in the washings before the current was applied, and as no food was present to invite its flow, it was evidently excited by the electricity. I suspected the rubber tube might, by its presence, excite a flow of gastric juice, so I left it *in situ* for ten minutes, then withdrew a little of the water and found it entirely free of acid. I then applied the constant current for eight minutes and hydrochloric was present in considerable quantity at the end of the application.

Subsequently, on many occasions, and in many different stomachs, we found free hydrochloric acid excited by the direct application of positive and negative galvanism, and by the faradic current. Direct electrization has not, with us, invariably caused secretion of gastric juice, but in the great majority of cases the constant current

has done so, while the interrupted has shown more numerous failures. These observations are, in the main, in accordance with those of Dr. Max Einhorn, published in his interesting and instructive paper entitled "A New Method for Direct Electrization of the Stomach," excepting that he experimented with healthy, and we with disordered, stomachs.

In several diseased conditions of the stomach we frequently find hydrochloric acid secreted in excess; notably of these, hyperacidity and dilatation. The cause of this lies in the disturbed or deficient innervation of the organ. This is also the cause of dilatation in many cases. More particularly do we see this emphasized in those cases which react quickly under the faradic current, and in a few weeks resume their normal size and tone. No measure is so effectual as direct electricity in the management of gastric dilatation with hydrochloric acid in excess. Knowing that the latter is secreted copiously under the influence of the current, it would seem, at first sight, to be contra-indicated. But clinical experience testifies as to its usefulness; and the benefit to the gastric innervation derived from its use quite overbalances the harm of a temporary increase in the flow of hydrochloric acid.

Direct electrization, especially with the constant current, is useful in cases of deficient secretion of acid; and this is manifest in the light afforded by such tests as Dr. Einhorn and I have made. Dr. Stockton has on record a case of intense gastralgia treated during the past winter, in which we never found hydrochloric acid present until we had used electricity directly several times. After that we regularly found it present at the proper time and in proper amount.

To recapitulate, then: 1. The secretion of gastric juice is excited by direct electrization in healthy,[1] and in many diseased conditions. 2. Sometimes in clinical work electricity fails to excite the secretion of hydrochloric acid. 3. Although in gastrectasia excess of hydrochloric acid is frequently present, direct electrization is not contraindicated. 4. In conditions of deficient secretion of gastric juice it is a most valuable therapeutic measure.

436 Franklin Street.

Clinical Department.

A CASE OF LAPAROTOMY FOR TUBO-OVARIAN DISEASE.[2]

By E. MAMMEN, M.D.,

Bloomington, Ill.

Mrs. Mary A——, widow, aged thirty-six, the mother of four children, youngest aged eight, oldest thirteen, began to menstruate at twelve years of age and has been regular ever since, with interruptions only for pregnancies and lactation, all of which were normal, including labors. There is no history of abortion. Health had always been fairly good up to February, 1887, when she was taken sick with what she described as "ulcers and falling of the womb." She was confined to her bed most of the time until September of the same year, after which she enjoyed good health to November, 1890. On November 6th I was called to see her at her home, making two visits. Her symptoms at this time were obscure—morning temperature normal, evening temperature 102° F. There was some tenderness over the abdomen, but no enlargement of either side. On my remarking that she might be sick for some time, she replied that she would go home to Olney, in this State, so as to be among friends. She departed a day or two later, and I did not see her again until February 21, 1891. She had returned to this city, and informed me that she was sick eight weeks at Olney. She was attended by a homœopathic physician, who told her she had peritonitis. She had fever, tenderness over the abdomen, vomiting, great prostration, and a slow convalescence. At this time a "lump" or "knot" had appeared in her right side, about the size of a hen's egg, but had again disappeared and could not be felt. Her menstruation had been regular all the time, and she was not aware of any uterine or ovarian difficulty. The right iliac region, however, was enlarged and tender, which enlargement, she said, had reappeared about three weeks previously, or about February 1st.

At the time of my visit (February 1st), physical examination revealed the following condition: On inspection, the right iliac region was enlarged and bulging (the patient was somewhat emaciated), and palpation revealed a semi-solid mass in which fluctuation could be felt. It was apparently smooth, about the size of a goose's egg, slightly movable, and lying entirely to the right of the linea alba. Vaginal examination disclosed the fact that the uterus was crowded to the left, and almost immovable in this position. Bimanual touch showed the tumor to the right of the uterus and capable of motion distinct from it. Dr. F. H. Godfrey, of this city, who examined the patient about this time, confirmed all of the above symptoms. The tumor was growing rapidly and its removal advised at the earliest date possible. On February 27th the needle of a hypodermic syringe was introduced a little to the right of the linea alba, near the fundus of the tumor, and about two drachms of an opalescent fluid removed. Microscopic examination of this fluid by myself and Dr. J. B. Taylor showed numerous Drysdale cells, but blood-corpuscles and pus-cells were entirely absent. All the symptoms collectively seemed to leave no reasonable doubt of the presence of an ovarian cyst. Meanwhile the patient's temperature ranged from 99½° to 101½° F., pulse 120 to 130. Both were taken daily. The cyst enlarged rapidly, and on March 9th, the day of the operation, had pushed its way up so that its position was nearly central and the fundus was two inches above the umbilicus.

The operation was performed by the writer, with assistance of Drs. Taylor, Guthrie, Godfrey, and Myers, on the morning of March 9th. An incision was made in the linea alba, about four inches long, midway between the umbilicus and pubes, and the dissection continued carefully down to the peritoneum. On opening the latter there was a gush of a small quantity of yellowish fluid and it became at once apparent that the tumor was closely and intimately adherent even at the point of incision, except on one side. On attempting to separate these adhesions the fragile nature of the cyst-walls caused a rupture of the sac, and instead of an opalescent aqueous fluid out gushed a large quantity of exceedingly fetid pus to the amount of two quarts or more. It was at once evident that we were dealing with a suppurating tubo-ovarian cyst. The pus was evacuated thoroughly before any attempt was made to remove the cyst. Its walls were so fragile that the rent enlarged during the flow of pus, and on exploring its interior a large quantity of cheesy material was evacuated, and pouches were found to project backward and upward beneath the transverse colon, backward and upward to the right toward the inferior surface of the liver, downward into the cul-de-sac of Douglas, and directly backward toward the spinal column. A hot saturated solution of boric acid was freely used for irrigating every part of this large cavity, as well as the peritoneal cavity, until all pus had been thoroughly evacuated. Then the cyst was ligated in sections as far as it could be separated from its very extensive adhesions. These adhesions involved the colon, mesentery, small intestines, bladder, and uterus. In view of the impossibility of separating these extensive adhesions it was deemed advisable to remove as much of the cyst as possible and leave the remainder. Every particle of the blood and pus having been thoroughly washed away, the

[1] Dr. Max Einhorn, MEDICAL RECORD, May 9, 1891.

[2] Read before the McLean County Medical Association, May 7, 1891.

cavity was cleaned with a solution of iodoform in ether and dried with sponges, and the wound closed with silk sutures. A large glass drainage-tube was inserted in its upper angle penetrating toward the left upper portion of the cavity, while a rubber tube was inserted into the upper right portion of the cavity, also a third tube of rubber was allowed to project from the lower angle of the abdominal incision. Thus thorough drainage was provided for. The wound was dressed with iodoform, carbolized gauze, oiled silk, and absorbent cotton. The time of the operation occupied nearly two hours. Pulse at this time began to weaken at 140. A hypodermic injection of brandy and hot applications soon caused the patient to rally, and by 4 P.M. reaction was fully established. (Before the operation—9.30 A.M.—the patient's temperature was 100.5° F.) Pulse, 120; temperature, 100° F.; she had voided urine twice, had no pain, and was cheerful. Next day at 4.40 P.M. temperature was 100.2° F.; pulse, 152. Dressing was removed, and the wound irrigated with hot solution of boric acid. Ordered ten drops tinct. digitalis to be given every four hours. At 10 P.M. temperature, 99.6° F.; pulse, 144. Next day at 8 A.M. temperature, 99.6° F.; pulse, 116. There had been some discharge from the drainage-tubes. They were removed and cleansed, and the wound was irrigated with solution of boric acid. Nourishment was taken freely every four hours. At 5.30 P.M. temperature, 99.4° F.; pulse, 108. Up to this time ¼ grain of morphia had been given every four hours to insure rest and prevent pain. This was now discontinued. On the 13th bowels were evacuated without medicine. Patient comfortable and cheerful. Wound dressed every morning and its cavity washed out with peroxide of hydrogen. The stitches were removed on the 17th and on the 19th the drainage-tubes from the upper angle were omitted and the lower one shortened.

The following shows pulse and temperature from March 12th to 20th: March 12th, A.M.: temperature, 98.5° F.; pulse, 116; P.M.: temperature, 99.8° F.; pulse, 116. March 13th, A.M.: temperature, 99.4° F.; pulse, 106; P.M.: temperature, 99.2° F.; pulse, 108. March 14th, A.M.: temperature, 100° F.; pulse, 116; P.M.: temperature, 99.4° F.; pulse, 120. March 15th, A.M.: temperature, 99° F.; pulse, 116; P.M.: temperature, 100° F.; pulse, 116. March 16th, A.M.: temperature, 99.2° F.; pulse, 112; P.M.: temperature, 100° F.; pulse, 120. March 17th, A.M.: temperature, 99.4° F.; pulse, 108; P.M.: temperature, 100° F.; pulse, 116. March 18th, A.M.: temperature, 99.4° F.; pulse, 108; P.M.: temperature, 100° F.; pulse, 116. March 19th, A.M.: temperature, 99.4° F.; pulse, 112; P.M.: temperature, 100° F.; pulse, 120. March 20th, A.M.: temperature, 100° F.; pulse, 120; P.M.: temperature, 99.8° F.; pulse, 116.

All went well up to this date. On the morning of the 20th, while emptying a syringe containing the peroxide, the patient suddenly complained of violent pain which was persistent. Evidently some of this fluid, or some of the decomposed pus which was carried along by it, had penetrated too deeply. One sixth grain morphine was at once given. On the following morning the patient was restless, and had vomited repeatedly. Temperature, 100.8° F.; pulse, 124. In the evening temperature, 103.8° F.; pulse, 156. There were evidences of peritonitis localized in the vicinity of the umbilicus. I ordered ten grains of tincture digitalis to be given again every four hours, five grains of acetanalid as required, and free purgation by citrate of magnesia, also tablespoonful of whiskey every two hours. On the following morning the temperature was 98° F. The patient was vomiting frequently. A teaspoonful of Epsom salts was given every two hours, until free watery catharsis set in, and this was continued during the afternoon. Five grains of acetanalid were given at bed time with one sixth grain of morphine The next morning the temperature was 100.8° F.; pulse, 138. Vomiting was less frequent. I ordered again a teaspoonful of salts every two hours. In the afternoon there was free watery catharsis. Temperature, 102° F.; pulse, 136. Digitalis continued. Acetanalid, grains five, morphine, one-sixth, at 8 P.M.

March 25th A.M.: Temperature, 98.4° F.; pulse, 118. From that time all symptoms of peritonitis subsided. The patient's temperature had gone down to 99° F.; pulse, 104; and all pain and tenderness had disappeared. Nourishment was taken freely and she was able to sit up a few hours daily. The bowels moved regularly.

Remarks.—The patient's cheerful aquiescence in all that was required of her, as well as her quiet courage, were helpful factors in the case.

The successful treatment of peritonitis by free purgation was well illustrated here. The saline aided in expelling the accumulated flatus from the bowels, as well as in depleting the turgid capillaries by free drainage. Acetanalid was used only to keep down high temperature, and morphine only when required to subdue pain and restlessness. Nourishment, at first, liquid; after ten days more substantial was given every four hours. On March 24th the patient asked for some beer, stating that it would relieve her vomiting. She was permitted to have it in small quantities, and it was found to relieve vomiting, as she expected. By the presence of this inflamed cyst the peritoneum no doubt became tolerant of the inflammatory process, rendering it less liable to acute peritonitis—a factor which had a marked bearing on the patient's recovery. The aspirating needle had withdrawn fluid from a small cyst lying upon the main cyst, showing that aspiration from one portion of a tumor may not always demonstrate the contents of the whole.

During the third week of April the patient suffered from la grippe, but has now (May 7th) fully recovered, and is able to perform her usual household duties.

ADVANTAGE OF COMBINING IODINE WITH GLUCOSE.

By F. P. MANN, M.D.,

SAN FRANCISCO, CAL.

THE remedial value of iodine is well known. But it is also a fact that full doses cannot be administered internally except in the form of iodide of potassium. As a rule in the various forms of disease to which free iodine is applicable any combination having an alkaline base is not desirable. In order to secure the specific action of a remedy adapted to relieve chronic disorders, and it is to this class of diseases that iodine is chiefly applicable, it is important that it should be to a certain extent cumulative and retained in the circulating blood for a sufficient length of time to exert its specific action upon diseased tissue. In glucose we have an agent capable of absorbing, or rather of occluding, free iodine so that this metalloid cannot be detected by either odor or taste, and thus combined can be administered in much larger doses than formerly employed without producing unpleasant symptoms. Another advantage in giving iodine occluded by glucose is found in the fact that as this substance occurs normally in the contents of the small intestine, in the chyle after the use of amylaceous and saccharine food, in the blood of the hepatic veins, and in the tissue of the liver in the form of glycogen, it is probable that glucose in thus occluding free iodine is itself protected from chemical change during the process of digestion by the antifermentative quality of the latter, and hence may be readily absorbed into the circulation, carrying in its embrace the iodine to be liberated during the morphological changes that occur prior to the formation of new blood-corpuscles. In the formula, thirty grains of iodine are dissolved in four ounces of water by means of one hundred and fifty grains of potassium iodide; to this solution is added twelve ounces of syrup as prepared by the sugar refineries and sold by grocers under the name of golden syrup, or sugar-house syrup, or molasses. This syrup contains glucose in combination with organic matter, and answers

the purpose quite as well as glucose manufactured from starch by the action of sulphuric acid, or other glucosides furnishing this substance in an isomeric form. The exact formula as above should be given to the druggist with special direction that simple syrup must not be substituted, this containing entirely crystallizable sugar will not take up the iodine, and the result will be a strong solution of iodine, which cannot be taken without serious inconvenience. To avoid mistake, I direct as follows:

R. Iodinii	℥ ss.
Potass. iodidi	ʒ ijss.
Aquæ puræ	℥ iv.
Syrup. fuscus	℥ xij.
Ess. gaultheriæ	ʒ ij.

M. Fiat sol. Sig.: Take tablespoonful between each meal with a little water. (Syrupus simplex must not be used.)

I have succeeded in producing the most satisfactory, I may say remarkable, results where potassium iodide, Ingol's solution, and syrup ferri iodidi, had signally failed. It is better in prescribing this formula to advise commencing the use of the medicine the day following that on which it is ordered, as some hours, about six to ten, are required in which to completely occlude the free iodine. I do not know the exact limit of this occlusion, but, if desired, a much larger proportion of iodine can be used than already named, and still remain odorless and tasteless so far as free iodine is concerned; though where a stronger combination is employed it would be advisable to commence with a smaller dose and increase it gradually.

AURAL HALLUCINATIONS CURED BY REMOVAL OF FOREIGN BODIES FROM THE EAR.

By W. P. SPRATLING, M.D.,

FIRST ASSISTANT PHYSICIAN NEW JERSEY STATE ASYLUM FOR THE INSANE, MORRIS PLAINS, N. J.

The following case is one of great interest, since it serves so clearly to show how dependent certain mental manifestations may be upon bodily derangements that appear simple enough when once understood.

W. C——, a man aged twenty-eight, a native of Ireland, employed as a common laborer, was admitted to this hospital, December 26, 1890. Ten months prior to his admission he began to hear "voices" and "noises," which commenced in the left ear and steadily persisted until the date of his admission here. These aural disturbances gradually became more pronounced and constant, and so annoyed him night and day that he began to suffer physically from the effect of the delusion. The following notes are taken from the house records:

"The voice is a woman's, which abuses him in the vilest language, or threatens, scolds, and pleads for caresses alternately, until his life has become unbearable, and he willingly comes here for treatment. Many times this voice tells him to kill persons or himself, but he has never had the inclination to obey its commands. Only in the silence of the night, when worried beyond measure by the constant mental torture, does he ever believe that it is, perhaps, a 'witch' something 'supernatural.' He has lately complained of dyspepsia, which he thinks is due to the influence exerted by the 'voices.' Insomnia is persistent. In the reception-room the patient made known his willingness to tell what the 'voices' just then were saying to him, which he told as follows: 'Kill me and I'll kill you,' 'I'll cut your throat,' 'I'm keeping a beer-store in your head,' 'You are a devil,' etc. He complains of pain in the left side of the head and in the stomach, and shows considerable mental depression. He is anxious to undergo any operation or form of treatment, and would even be 'deafened' as he expresses it, if in being so, the 'voice' could be silenced."

He was sent to the infirmary ward and given at night ʒ ij. of paraldehyde with ⅙ grain morphia. Upon testing his hearing the next day, it was found to be much impaired on the left side; the ticking of a watch could not be heard at a greater distance than six inches. On the right side it could be heard four feet away. The "voices" annoyed him so that he did not sleep any the previous night, notwithstanding the hypnotic he had. Some days later I decided to syringe out the left ear, in hopes of removing inspissated wax, or some foreign body, which, if taken away, might terminate the hallucinations of hearing. Using a regular Davidson syringe (as I could get no other just at the time) and, guarding against any rough contact of the small metal nozzle with the internal parts of the ear, I gently injected a pint of warm soap-suds, and was gratified to find a generous *débris* coming away in the shape of dried wax and pieces of tobacco the size of a split pea. Afterward the auditory canal was carefully dried and absorbent cotton inserted. The patient was hopeful from the first that the operation would relieve him of the "voices," and I endeavored to impress him with the fact that it most likely would. Within twelve hours after the syringe was used he told me the "voices" were leaving him, and two days later they were entirely gone. He remained here two weeks longer, but had no further trouble, and at the end of that time was discharged recovered.

Progress of Medical Science.

Salts of the Sea Air.—Dr. Friedrich, of Dresden, combats the view that winds, especially easterly winds, cause the removal of the salts from the sea water and their more or less general dispersion. The author quotes in support of his own view a large number of old and modern works, and adds to these the results of his own experiments. From these it appears that sea air as such contains no salts at all, and that its saltness, both at sea and on the shore, results from infinitesimal particles of the water dispersed by the waves and tide, while currents of air cause the further distribution of the finest saline particles. He denies that evaporation contributes to the presence of salt in the sea air. The salt found in plants near the coast has the same origin as that in plants at some little distance. It is caused by meteoric water, which always contains chlorides. These chlorides are present in greater quantity on the coast because the humidity is greater and more frequent, and larger deposits take place. The value of the sea air for therapeutic purposes is also, he believes, not due to the presence of salt, but to the greater humidity, purity, and density of the air, as well as to its more uniform composition. In view of other observations, Dr. Friedrich does not dispute the favorable influence of the greater quantity of ozone, but he lays particular stress on the fact that, to be of good and permanent effect, the treatment of serious cases, especially of chest affections, must be undertaken in a suitable climate and a favorable situation. Even there a real improvement and permanent cure cannot be expected in from four to six weeks, but requires a repetition of the treatment or a stay of some months.—*Deutsche Medicinische Zeitung.*

Experimental Peritonitis.—Dr. Waterhouse, in a series of twelve observations, confirmed the results of Grawitz, and negatived those of Pawlowsky, that a considerable quantity of a virulent culture of the staphylococcus aureus might be injected into the abdominal cavity without causing peritonitis. Also, when the staphylococcus is mixed with an untried medium, it causes no disturbance if the mass can be readily absorbed; the greater the difficulty of absorption, the more certain the production of peritonitis. Trials were made with agar-agar, gelatine, and coagulated blood, each containing the staphylococcus, and the results were positive. Pus containing the staphylococcus possessed strong pyogenic properties, due, the writer thinks, more to its contained chemical substances

than to its micro-organisms. The observation of Grawitz, that when the infection was introduced through a wound in the abdominal wall peritonitis followed, was not confirmed. When the wound was pencilled with turpentine an abscess was produced, but only in cases where the wound involved the peritoneum; if it extended only to that membrane, and not through it, no abscess was caused. When artificial effects were produced in the peritoneum, injections of the staphylococcus caused peritonitis; a similar effect was produced in animals affected with ascites. A strangulation of the intestine for some hours, similar to that produced by a hernia, invariably caused peritonitis after the injection of the staphylococcus into the abdomen or blood-vessels. The same result was reached if the coccus was injected subcutaneously, but not if it was placed in the intestine. A few observations upon man has shown that the staphylococcus may be injected under the healthy skin without danger, but that suppuration follows if the absorption is hindered or the normal conditions are altered by passive hyperæmia.—*Journal of American Medical Association.*

Damage to the Arms at Birth.—Dr. Jules Comby's interesting notes on obstetrical paralysis in the newborn are published in the *Bulletin de la Société Médicale des Hôpitaux de Paris*. In the first case there was paralysis of the left arm and œdema of all four extremities. The shoulder had presented, turning was necessary, and the mother died. Faradization cured both the paralysis and the œdema. In the second case the shoulder had also presented, turning had been performed, and the left arm was paralyzed, but there was no œdema. Faradization proved of little value; the patient, however, was several weeks old when the treatment was commenced, while the first was only eleven days old. The third case was grave. The child was six months old when observed by Dr. Comby, and suffered from total paralysis of both arms. The breech had presented, the mother's pelvis was contracted through rickets, and the child required firm traction before it was delivered. Born asphyxiated, it was not revived without great difficulty. The arms hung limp and cold from the first. The child grew and flourished, but no treatment was of avail for the paralysis; at thirteen months the child looked very healthy, but the arms hung down, perfectly insensitive even to needles. Faradization was not commenced till the sixth month, no doubt far too late.

Dr. Roullaud has already worked out the mechanism of obstetrical paralyses at birth. Spontaneous paralysis may occur through the clavicles being pushed inward during the passage of a broad-shouldered fœtus through a narrow pelvis. The fifth and sixth cervical nerves are thus compressed. The forceps may directly contuse the brachial plexus; the finger or blunt-hook applied to the axilla to disengage the shoulders may press in the clavicle and damage the cervical nerves. These nerves have been damaged, at least in one case traced into adult life, by constriction of the child's neck by a coil of umbilical cord. The forking of the fingers over the nape—a well-known manœuvre in breech cases—may cause paralysis by direct damage to Erb's point. Pressure on the shoulders and direct traction on the arms may cause damage to the whole cervical or brachial plexus. Still graver results may follow clumsy handling of the arms, shoulders, or neck of a fœtus. Thus, the branch between the sympathetic and the first dorsal nerve has been injured, the effects being seen even in the pupils. Again, a child may be maimed for life by manipulation of its arms at birth.

Belladonna in Labor.—Dr. Asher, of Lithgow, New South Wales, advises the use of belladonna in the early stages of labor, having found it of immeasurable benefit, saving considerable pain to the patient and materially diminishing the expected period of the labor. In primiparæ, after a prolonged period of pains of more or less intensity, and with but little dilatation of the os, as well as in the more intense condition of a completely rigid os, where, with extreme contractions, no dilatation whatever occurs, he has given large doses of belladonna with marked effect. He usually prescribes a reliable tincture of belladonna in doses of twenty to thirty minims every hour, or oftener; and satisfactory dilatation usually follows the first or second draught.—*The Australasian Medical Gazette.*

White Infarct of the Placenta.—Dr. Finzi, who has made a number of observations on placentæ in cases where the children were either stillborn or died shortly after birth, states that the most frequent morbid condition found was the so-called white infarct (*The Lancet*). It is occasionally confined to the lacunæ, and is due to a thrombosis occurring in them, which is caused sometimes by a retardation of the circulation, at others by necrosis of the villi. In the latter case the villi may be seen to be invested with a very delicate mosaic of exceedingly minute polygonal, transparent, nucleated cells, which may be an atrophic condition of the normal epithelium. Generally the infarct is situated in the tissue of the decidua, and consists of an exudation rich in white corpuscles and in nuclear detritus, which elements are found infiltrating the basal layer of the decidua, or collected in foci in certain points in the fibrous tissue. In other words, the so-called infarct is the result of a placentitis, and sometimes hemorrhage may be seen to have occurred in the substance of the decidua, proceeding from the utero-placental vessels. Secondary thrombosis of the lacunæ, from retardation of the placental circulation, not infrequently follows this infarct of inflammatory origin; and when this is the case there will generally be discovered a history of syphilis, tuberculosis, or pelvi-peritonitis.

Prominent Muscular Fibres Mistaken for Vesical Calculus.—Professor Antal, of Buda-Pesth, describes a case of a traumatic affection of the bladder, where the cystoscope proved of great service. A railway guard received an injury from getting between the buffers of two carriages, which produced retention of urine. When catheterized no blood was found in what was drawn off, and therefore it was concluded that there was no rupture of the bladder; the retention, however, continued for some time, but ultimately passed off. Some two years after the accident, after a beer-drinking bout, retention again occurred, and the surgeon who was called in to relieve it, feeling a rough surface in the bladder with the catheter, thought there was a calculus, and sent the man into hospital. Dr. Antal found that there was incompetence of the bladder, and that the urine was free from any abnormal ingredient. On examination with the cystoscope the internal fibres of the detrusor, or muscular coat, were seen projecting above the surface, enclosing irregular spaces. The mucous membrane covering the projecting fibres was of a pale yellowish-red tint, while that of the more deeply lying spaces was of a much darker red. The hyperæmia of the mucous membrane was by no means marked. The fundus of the bladder presented no abnormal conditions, those described affecting, however, all the rest of the internal surface. The catheter was passed twice daily, and in a very short time the incompetence was cured, and a subsequent cystoscopic examination showed that the trabeculæ had become very much less prominent. Professor Antal believes that the incompetence and "trabecularismus" which came on two years after the injury are to be ascribed to a disturbed condition of the innervation, first, of the detrusor, or muscular coat of the bladder, and afterward of the sphincter.—*The Lancet.*

A New Method of Inducing Premature Labor.—Dr. Schrader, of Hamburg, has published a method of inducing premature labor based on his observation that cold is a greater excitant of the nervous, and consequently also of the muscular, system than warmth. Continuous irrigation at the temperature of 45° F. is impracticable on account of the pain it causes, but a cold douche al-

ternating with a warm one can be borne. Dr. Schrader connects a vaginal glass tube by means of a T-shaped piece and the necessary india-rubber tubes to two irrigators, one of which contains the cold and the other the warm water. By allowing now one instrument and now the other to work, cold or warm water may be sent through the vaginal tube into the vagina. Two people are required—the one to fill the irrigators, the other to work the douche. For each sitting about twenty-four litres of cold and half the quantity of warm water at 112° F. are required, and the douche has a fall of about one metre and a half. The irrigation begins with the warm current, and before the cold water is turned on pressure is made on the perineum with the vaginal tube, so as to allow all the warm water to run away from the vagina. The same plan is observed before the change from cold to warm, by which means the alteration in the temperature as felt by the patient is always sudden. Each time about two litres of cold and half the quantity of warm water are used. The douche is generally repeated about every hour and a half until labor is active enough to make its continuance probable. Of eighteen women treated by this method exclusively, and four others who were partly so treated, one died of eclampsia twelve hours after delivery, but all the others made a good recovery. The eighteen women who were treated by the douche exclusively had twenty children, of whom fifteen, that is, seventy-five per cent., were alive. These cases required on the average ten douches and a half; in half the number three douches and a half were sufficient.—*Centralblatt für Gynäkologie.*

Syphilis of the Lung.—Dr. Lancereaux states that pulmonary lesions are rarely met with, but when seen pathologically the anatomical changes are sufficient to identify them. They occur in the form of indurations and gummata. Syphilitic sclerosis differs from tuberculous induration of the lung in many ways. It is met with, as a rule, in the lower or middle lobes rather than at the apices, and in the form of bands and fibrous tracts which are not welded together into a compact mass, but may enclose islets of lung tissue, generally more or less emphysematous. The fibrous tissue is not pigmented. The bronchi in relation with these indurations are often flattened, and the alveoli are filled with exudative fluid containing leucocytes and desquamated endothelial cells. The pleura is often thickened and adherent about such diseased areas, and the surface of the lung is puckered and furrowed in much the same manner as the surface of a cirrhosed liver. Syphilis and tubercle may be combined in the same organ, but the appearance of the sclerosed tissue is distinct in each. Cavities and the presence of fresh tubercle in other parts will aid the diagnosis. It is probable that many cases of chronic tuberculous disease have been classed in literature as syphilitic. Chronic pneumonia gives a firm, compact, indurated mass, soft and glossy to the feel, and not puckered on the surface. Leprosy of the lung is very rarely seen, and the characteristic bacilli would serve to distinguish it. Gumma of the lung is met with rather more frequently than syphilitic induration, but is still very uncommon, and no case should be accepted as such without absolute proof. The details of a case are quoted, and from the microscopic structure of the gummatous masses Dr. Lancereaux believes that they are formed by peripheral increase from a starting-point of peri-arteritis. Fatty degeneration takes place in the centre of the mass, but the remains of alveolar walls and flattened epithelium can often be recognized. The parts around may be thickened by proliferation of lymphoid cells and congestion, and around the whole mass, which is indicated under the term gumma, there is always a zone of indurated tissue more or less firm and vascular. The fatty degeneration of the centres of the masses may lead to liquefaction, and the evacuation of the fluid thus produced causes considerable irritation of bronchi. Cicatrices are often found in the neighborhood of the gummata, and a dry pleurisy is usually set up which results in dense adhesions. Syphilis never causes a purely serous exudation in the pleura. The diagnosis by physical signs is exceedingly difficult, and the symptoms are apt to be very misleading. Cough, hæmoptysis, and muco-purulent sputum may all be present, but the absence of the bacilli from the latter will form an important element in the diagnosis. Wasting, as a rule, only occurs when the liver or spleen is attacked by the disease, and it may thus happen that wasting will be progressive while the condition of the lung is improving. The latter tends to become stationary after a while, and if other organs are not affected the prognosis is good. The suspicion of syphilis should always attach to lesions beginning in the lower parts of the lung, and slowly progressing without the production of fever.—*Union Médicale.*

Elimination of Iron by the Bile.—That iron is present in the bile has been known for a long time, but the exact quantity eliminated by this channel and its significance have perhaps been exaggerated by some physiologists. Hamburger's researches, although ten years old, are still of great importance, for he established the fact that the largest part of the iron introduced into the body, either naturally in the food, or given in the form of preparations of iron, is eliminated in the fæces, a very minute trace by the urine, and excessively little by the bile. Thus a dog, in the course of thirteen days, received 180 milligr. of iron, and in the same time 136.3 milligr. were eliminated by the fæces, 38.4 milligr. by the urine, and 1.8 milligr. by the bile. He also showed that the iron eliminated by the bile is but little influenced by variations in the amount of iron introduced by the mouth, so that the iron in the bile must be regarded as an index of the hæmatopoietic or hæmatolytic action of the liver. Dastre subjected a large dog, with a biliary fistula, to a strict dietary, and collected most carefully the bile excreted daily. He finds that the proportion of iron in the bile excreted is very variable. As a mean, it is 0.94 per cent. of the dry residue, although there are very considerable variations even in a regular and exactly similar diet, so that Dastre also finds that the hepatic iron depends more on the blood formation or blood destruction in the liver than on the alimentary conditions. The quantities of iron excreted in the bile of a dog weighing 25 kilos (55 pounds) vary from 2.34 to 0.09 milligr. per day per kilo weight of the animal.—*Archives de Physiologie.*

Intubation in Germany.—Dr Ranke, writing in the *Münchener Medicinischer Wochenschrift*, says that intubation is to be preferred during the first year of life, but that tracheotomy gives better results in older children. He considers the risk of intubation less than that of tracheotomy, if proper tubes are carefully used. The number of cases upon which he bases his comparison is rather small, and the difference in favor of tracheotomy is slight. If, in a case of intubation, it is impossible to remove the tube in eight or ten days, he advises that the operation of tracheotomy be performed.

Permanganate of Potassium in Diphtheria. — Dr. Netzetzky says that his twenty-two years' practice convinced him that the best treatment of faucial diphtheria consists in an energetic use of permanganate of potassium. The drug should be administered in the shape of paintings and gargle. The following strong solution should be employed :

℞ Potassii permanganatis..... ʒ j.
Aquæ destillatæ ..... ʒ j.
M. Sig.: To paint the affected surface every three hours.

For gargling, which is to be repeated as often, a teaspoonful of the same solution should be mixed with a tumblerful of boiled water.

In those cases in which the child is unable to gargle, the following mixture should be given internally :

℞ Solutionis hydrogenis superoxydati, two per cent. ʒ ij.
Glycerinæ..... ʒ ij.
M. Sig.: A teaspoonful every two hours.

Hypnotic Action of Atropine and Duboisine.—Dr. Ostermayer, of Buda Pesth, draws the following conclusions from a number of experiments made on the action of atropine and duboisine: 1. Atropine in doses of $\frac{1}{64}$ to $\frac{1}{32}$ of a grain is an undoubted sedative in maniacal cases, and is indirectly a hypnotic in so far as the reduced reflex irritability which follows its administration tends to favor sleep. 2. It is not to be compared with the safe and prompt action of hyocine in this respect, although the amount of depression which follows its use in medium doses is much less likewise than that which is caused by hyocine. 3. From repeated employment the organism becomes habituated to its use and the effects become accordingly less, or even may be entirely absent. 4. Unfavorable complications, with the exception of vomiting and diarrhœa in one case, are never observed. 5. Atropine frequently has, in the author's hands, succeeded in producing a sedative effect where hyocine and morphine had proved entirely inert.

From the above it would appear that atropine in certain cases may perhaps possess some sedative properties, yet there is so much to be said on the opposite side of the question that it is doubtful whether its use will ever become general. As regards duboisine, the author concludes that, in excitable conditions and various mental affections, duboisine is comparable to hyocine, and is free from any of the objections which may be urged against the use of the latter. 1. The sedative action of duboisine may be observed within ten or fifteen minutes after the injection. 2. Duboisine's prominent action is a sedative one, and sleep ordinarily follows within twenty to thirty minutes after its administration. 3. In states of extreme excitement $\frac{1}{32}$ grain to $\frac{1}{24}$ grain are required in simple insomnia, and $\frac{1}{16}$ or $\frac{1}{40}$ grain will usually suffice. 4. Symptoms of poisoning or unfavorable after effects were never noticed. 5. The action of this remedy becomes weaker under prolonged use. The remedy was used by the author in 1 per mille solution.

The author likewise claims that the system becomes habituated to the use of hyocine as is the case with atropine and duboisine. In fact, he seems to regard duboisine as quite as useful a remedy as hyocine, as regards its activity, and preferable to it on account of its greater cheapness.—*Therapeutic Gazette.*

A New Disease in Africa.—Kaoumponli is the native name of a disease, hitherto unknown to European medicine, affecting the inhabitants of Central Africa. The disease begins with a rather intense fever, followed by marked general debility and an eruption in the form of papules and pustules, and sometimes by a profuse diarrhœa. The eruption is found on the neck and in the axillæ, but seldom on the arms. On the second day the fever reaches its height, the pulse becomes hardly perceptible, and the respiration becomes slow and rather labored. On the third or fourth day the symptoms pass away and the patient awakes as from a deep sleep. The disease is, however, frequently fatal, death occurring apparently from the intensity of the fever during the first or second day. The disease is of a very contagious character, almost the entire community being attacked nearly simultaneously when once it has made its appearance. But it affects the natives only, not only Europeans and Arabs, but even negroes from the coast, being immune to its attacks.

Pyoktanin in Foot-and-Mouth Disease.—Professor Eggeling, of England, has employed methyl blue with success in the treatment of foot-and-mouth disease in cattle. His method is to syringe out the affected parts with a one per cent. solution.

Defending the Use of Opium.—In a recent debate in the English Parliament upon the cultivation of opium in India, the use of the drug was defended by a medical member named Farquharson. He said that free indulgence in opium was far less injurious than that in alcohol, and asserted that there was no finer race of men anywhere than those natives of India who used the drug habitually. England has never lacked apologists within her own borders for her inhumanity in promoting the increase of the consumption of this drug.

For the Cure of Snake-Bite.—Mr. Dinshah Ardeshir Taleyarkhan, the Municipal Commissioner of Baroda, India, has published a pamphlet in which he offers some suggestions concerning the cure of snake-bite by means of inoculations of the blood-serum of immune animals. The common weasel is, he says, proof against snake-bites, and it will attack and kill any snake that it may come across, never suffering in the slightest from the serpent venom. He suggests therefore that the blood-serum of this weasel (or mongoose?) be injected in case of snake-bite, and believes that experience will show that this is an effective antidote against the poison.

Shaving with Vaseline.—A writer in the *Druggists Circular* calls attention to the value of vaseline as a shaving cream. The beard is said to be rendered as soft as when soap is used and there is no resulting irritation of the skin.

Strychnine and Snake-bite.—A controversy is going on in the *Australasian Medical Gazette* as to the value of strychnine in snake-bite, the generally approved opinion being that it is an efficacious remedy in this accident.

Sulphate of Magnesium in Dysentery.—The following is the method employed by Dr. Leahy (*Lancet*) in the treatment of dysentery. A drachm of the saturated solution of sulphate of magnesium, with ten drops of diluted sulphuric acid, is given every hour or two until the stools have become copious, feculent, and free from blood and mucus, the temperature has fallen, and the pain and tenesmus have ceased. When the stools are normal in appearance, and number only two or three in the twenty-four hours, an ordinary astringent mixture of acid with laudanum or tincture of Indian hemp, or a pill containing extract of opium, is usually all that is necessary to complete the cure. The patients are of course dieted with the greatest care.

Faradization in Incontinence of Urine.—Dr. Jamin reports a case of incontinence in a girl aged fifteen, where internal medication had failed of any result, in which a complete cure was obtained by faradization of the urethra—the negative pole in the urethra, and the positive on the thigh.

Syphilis Not of American Origin.—It has been supposed by some syphilographers that syphilis was brought from America by Columbus' sailors on their return from the discovery of the New World, and that Europe owes this boon, as well as those of tobacco, potatoes, and cinchona, to the western hemisphere. Later investigations, however, have pretty well disproved this theory of the origin of the disease, most of the modern authorities attributing the rise of the scourge to a much earlier date. A poem on the "contagious and cursed bubo," written by Francisco Lopés, of Villalobos in Spain, nearly four hundred years ago, has recently been discovered in the royal library of Madrid and republished. In this work, published in 1498, and of course written still earlier, the author describes nearly all the lesions now recognized to be those of tertiary syphilis. This would imply that he had seen a great number of cases, and it is hardly probable that there would have been very many cases showing tertiary lesions had the disease been introduced only five years before by Columbus' companions, who returned from their first voyage in 1493.

Retro-ocular Neuritis following Influenza.—Dr. Epéron calls attention to retro ocular optic neuritis occurring as a sequela of influenza, and reports five cases of this kind that he has seen in his own practice.

MEDICAL RECORD:

New York, June 13, 1891.

NEW RESOLUTIONS FOR FRANCE.

THE different phases of all the recent discussions before the French Academy of Medicine concerning the forthcoming depopulation of France, have been consolidated in brief in a report by Dr. Jules Rochard. The entire academic commission, consisting of Dr. Rochard, himself, Brouardel, Thos. Roussel, Roger, Guéniot, Javal, and Lagneau, are in perfect accord in regard to the new resolutions, and it is highly probable that the Academy as a body will adopt them. But how about the public authorities? One pretty sure way to shove hygiene to the wall, at least in Anglo-Saxon countries, is to season it with legislation. This is always caviare to the multitude and not to the public taste. Five of the new resolutions are well enough, so says the *Journal d'Hygiène* for March 26, 1891. But the others cause our esteemed contemporary a deep sigh for the divine principles of the rights of man, the principles of other days. Science is a meddlesome creature at best. And now, misguided possibly but with kind intent, she aims a direct blow at the great republican trilogy in the effort to replace it by that fatally prophetic word, which is nevertheless the ideal of progress—compulsion! Like the poor beggar in the opera who always had the blessed hope of sleeping in a bed, the French journal of hygiene is evidently sustained by the cheering thought that the powers that be may not enforce the laws now in the air. The ten new resolutions that are innocent enough in appearance, may contain something between the lines that is inimical to liberty, equality, and fraternity, though it is a little difficult to understand how the same petard can hoist all three.

Five of the new rules refer to compulsory vaccination, to a vaccine service, and to the isolation of small-pox patients. Evidently these are the five that meet with the approval of our French contemporary. One provides for the protection of young children, two deal with the sanitation of cities, one considers the subject of paternity, and another the regulation of prostitution and the possible mitigation of the ravages of syphilis.

All this, the whole decalogue, seems well enough in its way. A government confronted by the problem of national defence and corporate integrity is wise to catch at any straws, whether scientific or legislative. But one cause of the evil tendency in modern French life has up to the present moment been utterly ignored. This is the fact that the women of France do so much work away from the fireside and the seclusion of home. French women have not time to become mothers. To them maternity too often means a definite entailment of daily bread. The situation involves serious questions of social economics. In communities where women and children do outside work, the combined wages of a man, his wife, and his children only equal those of the man alone in districts where the husband and father is the sole bread-winner. There are abundant and reliable statistics to prove this.

It is a serious loss to a nation when a large proportion of its women do outside work and are engaged in non-original production, in work that men can do just as well. The state, if it is to remain a state, must reap the benefit of best feminine efforts. Men are more than things. To turn feminine intelligence, affection, beauty, and all the fostering care that character needs for its inspiration and development into the manufacture of things is a wicked and cruel waste. "What France most needs is mothers," said the great Napoleon. And to day the French can repeat his words with bitter emphasis. Their women have engaged in every kind of career, from the construction of frills and furbelows up to that of highest excellences in literature and art. And it has not paid. Such social order is only seemingly progressive. It marks an epoch, a stage of pure expediency, but not necessarily an advance except in comparison with tyrannous times.

The forthcoming depopulation of France may be an affair of medicine and politics. It is evident that it has a social economic side as well; and to be successful, all radical schemes to increase the birth-rate must include a consideration of this important factor.

SHOULD HOSPITAL SUPERINTENDENTS BE PHYSICIANS?

THIS question comes up periodically in both the daily and medical papers. It is somewhat difficult to answer with an unqualified yes, or no. The duties of the office going under the name of superintendent vary much in different institutions. To any one familiar with the workings of our large metropolitan institutions, it is manifestly impossible for any one man to care for both the business and domestic departments on the one hand and the actual detailed management of the patients on the other. Either division of duties requires the entire time of one person. There seems to be an impression abroad that much of the alleged "red tape" of our hospitals is due to the fact that in the majority of instances the superintendent is not a medical man. This we think a wrong view. With us the resident house physician or surgeon is the executive officer of the medical board as apart from the superintendent who represents the trustees. The superintendent is of course the deciding power in doubtful cases. If he is to look out for the patients, he must delegate the management of the domestic and material departments to a subordinate. If he cares for the latter, his management of the former must be nominal rather than real.

It is a great problem in charity administration to accomplish the greatest results with the least possible

duction and spread of contagious disease. We have a National Board of Health, it is true, and we have a competent army, navy, and marine hospital medical service. But the control of the country's health in its broadest sense, is at present exerted along too many channels to be of the highest possible efficiency. The advantage of having one central officer to whom all questions could be referred is apparent. When sudden epidemics arise or other emergency where prompt action is necessary, quicker means can be taken to bring preventive measures into play from this centralization of authority.

There is, however, a great objection in our mind toward the establishment of a new national department. We think it a weak plea to allege that such action would give greater prominence to the profession in general, and would be an acknowledgment of its worth, more fitting than any hitherto made. The country at large has never withheld its due meed of praise from the meritorious services of its physicians. In no land so much as in our own does the worthy possession of a medical degree meet with more cordial feeling. It is only among the lower orders of our foreign population that the province of the health officer is disputed. Our custom of changing cabinet officers every four years would bring the position into politics, and we should have the humiliation of having physicians discussed not with reference to their scientific attainments but with reference to their "availability," and "power" to bring their own State into line.

We have too many office-holders already without the addition of another department with its head, chiefs of divisions, clerks, messengers, etc. At the same time it may well be questioned whether or not the management of the country's health cannot be carried on more advantageously than at present. Plans well enough for a century ago may not be the best for to day. As to the direction these plans shall take, is a matter for long and thoughtful consideration. It would have been better if the Association had considered the matter longer in committee before taking public action. We are apt to forget the word cabinet does not occur in our national constitution at all. For many years there were only four departments. By 1849, the seventh had been formed. In 1888, the eighth and last, that of agriculture came into existence. Many patriotic citizens have had serious doubts as to the advisability of this latter proceeding. Yet, as this is essentially an agricultural country, such a department would seem at least justifiable. But the office of the cabinet is simply that of an advisory board to the President. It is an application of the principle of the division of labor to the carrying on of the government. These positions though always filled in the main by worthy men are yet in spite of all the growth of civil service ideas, political plums to be dealt out for party services. To add one more to the basket would harm rather than benefit our profession and immensely lower its dignity.

There is, however, room for this question—Could not a new bureau be created in one of the departments already existing; its head to be responsible to the President through the medium of only one man, the corresponding cabinet officer. The tenure of office of the new official should be independent of all the coming and going of parties. In certain lines already we find such a state of affairs, as in the Smithsonian institution. Let us rather find our political ambition in fulfilling our duties as citizens in loyalty to our local societies and health boards. So far as we have observed, the new demand comes from the western section of the country alone. That it will be granted, no one, even its proposers can hardly expect. They must bring forward stronger arguments. They have not yet made out a case.

THE ABORTIVE TREATMENT OF SYPHILIS.

The loathsome nature of pox; the great difficulty and uncertainty of thoroughly eradicating the disease from the system, when once firmly established, has made the dream of its early cure a pleasing one. The abortion of gonorrhœa has received a comparatively greater amount of attention, but when we stop to consider the dangers attending the present methods deemed necessary to effect this purpose, the freedom from systemic infection, and the possibility of bringing about a cure within a reasonably short time by safer means, we realize how much more to be desired would be a sure method of stopping short a syphilitic infection. For two hundred years excision of the chancre has been practised, in the hope, at times apparently realized, that in removing the initial lesion of the disease the system would escape. Strange as it may seem, after these two hundred years, we cannot yet say just what valuation should be placed upon the method. Some observers have claimed [illegible] while others have seen only failures follow

diabetes, albuminuria, etc. These rules for undertaking the excision were given three years after the author had expressed his belief in the inutility of the operation. His subsequent experience has, however, led him to regard the success of abortive effort as a possibility. He relates a case in which a lesion believed by him to be a true chancre was excised in 1884 (the woman from whom it was contracted being under his care, and surely syphilitic). The patient was kept under constant observation for about four years without treatment and never showed any further signs of syphilis. Leuger has communicated a similar instance.

Mauriac already in 1881 expressed his belief in the inutility of this attempted abortion, claiming that excision does not attenuate the near or remote consequences of the intoxication.

Wickham points out quite justly that a well-established true chancre may at times not be followed by secondary and tertiary accidents, or may be accompanied by very discrete lesions only, and hence an error may enter into deductions drawn from the patient's freedom from symptoms after excision. It would, however, not be at all likely that any large number of these mild cases would occur in a given series of excisions.

While it is too much at the present time to claim with Diday that if the excision does not succeed it is because it was not done completely enough, it would still be well for future investigators to make sure that they operate early enough, and include in their cut sufficient surrounding tissue to make it reasonably certain that any outlying cells, bacilli, or virus, which might still be harmful to the system have been removed along with the indurated lesion.

News of the Week.

A Society of Hygiene in Havana.—Dr. D. Antonio Gonzalez Curquejo, of Havana, proposes the organization of a Society of Hygiene in Cuba. The idea meets with hearty approval by *El Repertorio Médico Farmacéutico* and *La Revistà de Ciencias Médicas*, respectively the leading pharmaceutical and medical journals of Cuba. Some recent contributions, from Sr. D. Francisco Paradela on the causes of insalubrity in the Port of Havana, and showing industrious research, cannot but give an impetus to the proposed society. The Section in Hygiene in the Cuban Medical Congress which meets in January next may serve as a convenient starting-point for the new organization. The intimate maritime commercial relations between our own ports and those of Cuba invest all sanitary progress in the latter country with peculiar interest

The Ohio State Medical Society.—The forty sixth annual meeting of this Society will be held in Sandusky, O., on June 17, 18, and 19, 1891. The programme is a very full and varied one, and contains the titles of thirty-five papers to be read during the session.

Honors for Dr. Lassar.—The French Government has conferred the Order of the Legion of Honor on Dr. O. Lassar, General Secretary of the Tenth International Medical Congress, held at Berlin in August, 1890, in recognition of his "great and successful labors" in the organization of the meeting.

Memorial to Professor Nussbaum.—A committee, which includes most of the leading members of the medical profession in Munich, has been formed for the purpose of erecting a fitting memorial of the late distinguished surgeon Professor von Nussbaum.

Comparative Cost of Medical Education in England and America.—According to the estimate of the Secretary of the Illinois Board of Health, the average fees for the eleven London schools are, exclusive of the examination fees, £118, 5*s.*; for the provincial schools £98. In addition, each student has to pay from 10*s.* to £3 matriculation to one of the degree-granting bodies; from £1 to £15 for the first examination; from £1 to £10 for the second; from £2 to £15 for the first degree or qualification examination. In some of the colleges in the United States all the fees do not amount to $300, and in at least one the whole course of study and the diploma can be had for $138.

Somewhat Uncanny.—The daily papers announce that Dr. Rachel Tenny, of Chicago, was called to Kansas City to treat her daughter. The patient gradually sank, and died in a few weeks. She was conscious to the end, and discussed her own post-mortem and her subsequent cremation. The post-mortem examination was conducted by the mother. The daughter had expressed a wish to be cremated, and the mother brought the remains to St. Louis for that purpose. The incineration took place today under the mother's direction.

A Death from Hydrophobia caused by the bite of a rabid cat is reported to have occurred at Asbury Park last week. Pet cats are now being closely watched.

Compressed Air and Creasote.—The technique of this treatment for consumption recommended by Professor Sée is as follows: "The patient is shut up in a metal chamber, hermetically closed, and compressed air, passed through creasote and eucalyptol, is made to enter slowly. The air in passing through these liquids is saturated, and arrives charged with a large quantity of these medicaments. The pressure must be slowly increased, and should not exceed a half atmosphere. The speed of delivery of the air saturated with the medicated vapors is from fifteen to twenty cubic metres per hour for a space of five cubic metres of capacity. The length of time the patient remains in the chamber is usually two hours, sometimes three or more, and no inconvenience ensues as the result of this procedure. The inhalations are made daily or more frequently." Professor Germain Sée has tried this method in twelve cases, of which one was a case of apical bronchitis, a second was a case of fetid bronchitis, and the remaining ten were genuine cases of tubercular phthisis, all of which, with one exception, had arrived at the stage of softening. The results obtained would appear to be surprising, a marked amelioration being in most cases observable, not only in the amount and character of the expectoration, but in the general constitutional condition, and in some cases, though not in all, a corresponding improvement in the physical signs. It seems to us that the treatment is identical with the pneumatic cabinet treatment except that the patient is confined for a longer time.

Death After a Dose of Salol.—Salol is usually considered a tolerably innocuous drug, but there are not wanting clinical observations which tend to show that, under certain circumstances at least, its use may be followed by dire results. Thus a case was some time ago reported by Aufrecht and Behm in which death followed its use in acute endocarditis, and more recently Dr. Chlapowski has published in a Bohemian medical journal an account of a case in which a similar fatal result followed a fifteen-grain dose ordered to a patient who was suffering from severe gastric symptoms, and who was being examined by Ewald's method.—*Lancet.*

A New Medical Aspirant.—The Chicago *Medical Record* is the title of a new monthly publication which starts as the organ of the Chicago Medical Society. It is edited by Dr. Archibald Church, and contains a number of interesting original communications.

New Method of Treating Varicose Veins.—At the German Surgical Congress, Dr. Landerer, of Leipsic, communicated the details of a new method of treating varicose veins. This consisted in the application of a kind of truss, that was applied like a garter, and by its permanent pressure on the saphena vein effected a cure. Pressure was obtained by an india-rubber pad situated on the inner surface of the truss and filled with water. The pressure was constantly kept up until the wall of the dilated vein was ulcerated through. He had adopted this method of treatment from an observation of a deceased colleague, Herr Ravoth, who treated varicoceles by the application of a truss. Professor Bardeleben remarked that Ravoth had himself often told him that his cures of varicocele had not been permanent; he feared that Landerer's procedure would not effect a lasting cure.

Effect on Offspring of Consanguineous Marriages.—Drs. Louis and Gustav Lancry publish, in *L'Union Medicale*, the results of their investigations on this subject. Their conclusions, based on a study of sixty-three consanguineous marriages, are that the marriage of blood relations tends to the diminution of the birth-rate, but that it has no prejudicial influence upon the children born of such unions.

Financial Losses of Sir Joseph Lister.—Every member of the profession will be sorry to hear that Sir Joseph Lister has, through the bankruptcy of John Taylor, a well-known London stock-broker, lost upward of eighteen thousand pounds. It appears that Sir Joseph Lister had entrusted Mr. Taylor with the money to invest in securities, instead of doing which he applied it to his own purposes.—*Hospital Gazette.*

Medical Fellowship.—Three fellowships of $5,000 each in the Harvard Medical School have been established by a gift from William S. Bullard.

Biological Study and the Anti-vivisectionists in England.—The London correspondent of the New York

The History of Tuberculin.—In four acts:

Act 1—Eureka.
Act 2—Vici.
Act 3—Ave, morituri te salutant.
Act 4—De mortuis nil nisi bonum.
Epitaph—Fuit.

—*Medical Press.*

Alumni Association of Bellevue Hospital.—At the last meeting of the Society of the Alumni of Bellevue Hospital the following were elected officers for the ensuing year: *President*, Egbert Le Feore; *Vice-President*, W. R. Townsend; *Secretary*, William N. Hubbard; *Treasurer*, R. J. Carlisle.

Lehigh Valley Medical Association.—The eleventh annual meeting will be held at the Mansion House, Mauch Chunk, Thursday, June 25, 1891.

Dr. George P. Cady, of Nichols, Tioga County, N. Y., died May 19, 1891, of apoplexy. He was fifty-eight years of age; was a graduate of Berkshire Medical College in 1855. Was one of Pension Examiners for Tioga County. Has been President of Tioga County Medical Society for fifteen to twenty years.

Medical Association of Missouri.—At the meeting of the above association, held at Excelsior Springs, Mo., May 19–21, the following officers were elected for the ensuing year: *President*, T. F. Prewitt, of St. Louis; *Corresponding Secretary*, John H. Duncan, of Kansas City; *Recording Secretary*, L. A. Berger, of Kansas City.

Prize of the Medical Society of the County of New York.—A prize of the value of $100 is offered by the Medical Society of the County of New York for the best essay by a member of the Society in good standing

short distance from the hotel. Excursion tickets over the various railroads may be procured at nearly all the stations. The delegates (corresponding included) are invited to bring their families with them. The members of the profession throughout the State and guests from other States, are cordially invited to attend the meetings and also to bring their families with them. Further information may be obtained by addressing Henry Mitchell, M.D., Asbury Park, Chairman of Committee of Arrangements, or William Pierson, M.D., Secretary of State Medical Society, Orange, N. J. Members who desire to present voluntary papers or reports of cases will communicate by letter with Dr. H. R. Baldwin, New Brunswick, Chairman of Business Committee.

The Late Dr. Fordyce Barker.—At a special meeting of the Medical Board of the New York Cancer Hospital, held June 1, 1891, the following resolutions were unanimously adopted:

Whereas, In the death of Dr. Fordyce Barker, Consulting Physician to the Hospital, this Board has suffered the loss of its oldest and most eminent associate, whose interest in the welfare of the Hospital, shown in his address at the opening ceremonies, was fully maintained until the close of his life;

Resolved, That we hereby express our grateful recognition of his services, and our pride in the recollection of his connection with our institution, and that we tender to the family of the deceased our deep sympathy with them in their bereavement;

Resolved, That we attend the funeral services of Dr. Barker, and that the Secretary send copies of these resolutions to the family, and also to the MEDICAL RECORD and the *New York Medical Journal*, for publication.

B. FARQUHAR CURTIS, M.D., *Secretary*.

A Medical Temperance Congress.—The managers of e National Prohibition Park, of Staten Island, invite presentative medical men from all localities in the nited States and the Dominion of Canada to meet in nference on the 15th and 16th of July next, in the eat Auditorium Building of the Park. The chief object the meeting is to be the comparison of views on the lationship of physiology and alcohol. Among the ques-ns to be discussed will be the following: "What are e Hereditary Effects of Drunkenness?" "Are there y Hereditary Effects that Follow Moderate Drinking?" To what Diseases are Inebriates More Especially Exsed?" "Is Alcohol a Poison?" "Is Alcohol in any nse a Food?" "What are the Proper Uses of Alcohol a Medicine?" "Is there Danger of Producing the rink Habit from the Prescribing of Alcoholic Medines?" "How Large a Percentage of Deaths May be tributed, Directly or Indirectly, to the Use of Strong rink?" "Should Alcoholic Liquors Ever be Used Expt Under the Direction of a Medical Adviser?" It is nounced that, at this Conference, all views will be given impartial hearing, and no restraint will be placed upon e discussion save that of the time limit. Many well-own medical men have already signified their willingss to participate in such a conference. Dr. Nathan S. avis, of Chicago, will preside at the Congress, and will ake the opening address. It is hoped that delegations physicians will be sent from every town in the country. he Congress will assemble at 10 A.M., July 15th and 16th, and continue its session for two days. It is expected that arragements will be made for reduced railroad fares. All communications should be addresssed to the Secretary of the Park Association, Colonel R. S. Cheves, West New Brighton, N. Y.

Society Reports.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, April 16, 1891.

ALFRED L. LOOMIS, M.D., PRESIDENT, IN THE CHAIR.

Is Embryotomy of the Living Fœtus Ever Justifiable?—DR. EGBERT H. GRANDIN opened the discussion on this subject with a paper (see p. 641).

As the Patient and Relatives View It.—DR. H. J. GARRIGUES thought we were not justified in viewing the subject entirely from the medical side; we must view it also from the mother's side and that of the relatives. The medical view must to a great extent depend upon statistics. These, in fact, were all that we had to go by. In this country we seldom saw the higher degrees of pelvic deformity, and most gynecologists and obstetricians necessarily had very little experience on which to base an opinion as to the justifiability of ever performing embryotomy on the living fœtus. They had to look to the experience gained in other countries, especially in Germany. All statistics previous to the time of antisepsis might be cast aside as of no practical value. Taking modern statistics, Wieder, of Berlin, had collected 215 cases of craniotomy, with a mortality of between five and six per cent. Other statistics of 135 cases of Cæsarean section gave a maternal mortality of about twenty-six per cent., and an infantile mortality of eight per cent. Leopold, the most successful of modern performers of Cæsarean section, had a maternal mortality of eight per cent., but he had also performed 92 craniotomies with no deaths. Taking these statistics into consideration, it could not be denied that Cæsarean section, even with all the modern improvements, offered dangers considerably greater than craniotomy; the chances of saving the mother were five times greater by craniotomy than by Cæsarean section even in the best hands. Laparo-elytrotomy showed a maternal mortality of seven out of fourteen cases since what might be called the tentative period, and a fœtal mortality of forty-three per cent. It must be remembered many of the children were dead before the operation. Emphysiotomy gave a maternal death of about fifty per cent. and a large infantile mortality. The only other resource was premature labor, and this was the proper thing to do if one saw the case soon enough. The mortality for the mother here was five per cent.; for the child, fifty per cent. It seemed to him that the proper course as between the several operations was to choose craniotomy, although there were, of course, exceptions. If there was a generally contracted pelvis it was better, he thought, to perform a Cæsarean section. He also thought we must distinguish between hospital and private practice, city and country practice. Where a full set of instruments and plenty of assistants were at command one would feel less hesitation in undertaking Cæsarean section. The ordinary practitioner would usually find craniotomy easier, although this operation sometimes proved very difficult. From a moral point of view, when it came to a choice between saving the mother and the child, he would not hesitate to sacrifice the child. He mentioned the fact that the Roman Catholic Church did not permit of destroying the life of the child. If the case waited until it died in utero, the mother's life would be greatly endangered. In patients of that faith, therefore, we had no choice but to resort to Cæsarean section.

Favors Elective Cæsarean Section.—DR. ROBERT A. MURRAY said that in this country we seldom found as great deformity or contraction of the pelvis as in the European countries, but we had more cases in which the child could not pass through a slightly contracted pelvis because of the large size of the head. The average size of the child at German clinics was 6.5 to 7 pounds, while here it was 7 to 7.5 pounds, which would make considerable difference in the size of the head. We had, then, to judge each case by itself, since the question of whether the child could be delivered through the pelvic canal depended not alone upon the size of that canal, but also upon the size of the head. When the child was dead, it became a question of only absolute indication. If there were sepsis in the womb, he thought it would be better to perform Cæsarean section; if the organ were actually contaminated, do hysterectomy. Embryotomy had little advantage over Cæsarean section in ease of performance. Although Leopold had had some deaths from Cæsarean section and none in embryotomy, yet the saving of child-life in the former should have some weight. He favored elective Cæsarean section, especially in hospital practice. Prior to the days of antisepsis the statistics showed that most of the successful cases of Cæsarean section in this country had occurred in country practice.

Theory and Practice.—DR. H. C. COE said that he had been called to a case very recently which illustrated the difficulty of acting out a theory. The labor had begun about thirty-six hours before, the membranes had ruptured twenty-four hours before, the head had not engaged, the child was alive, the mother in good condition, forceps had failed. The question of Cæsarean section was raised, the husband left it with him to decide, but the other physicians opposed it, favoring embryotomy. They asked him if the woman were his wife would he have Cæsarean section performed? Answering candidly, he said he would not. He then tried version, did not succeed, the child had meantime died, and he performed embryotomy. The operation was difficult, the mother's chances would probably have proven as fair under Cæsarean section. She recovered. Had the case been in hospital practice, instead of private practice, Cæsarean section would have been performed.

One of the chief difficulties in deciding on what course to pursue was that many cases in which we expected to have to resort to Cæsarean section or embryotomy were actually delivered spontaneously. The statistics of craniotomy in this country could not be compared with those in Europe, for here physicians frequently overlooked slight contractions, and prolonged attempts were made at extraction before embryotomy was resorted to, and the last operation added too much to existing shock for the patient to rally. He thought a great mistake had been made in trying to lay down positive indications for Cæsarean section or craniotomy based on the size of the pelvic diameters, leaving out of consideration size of the head. Personally, he favored elective Cæsarean section in hospital practice, but it seemed a question whether it would in this country ever be adopted in private practice.

Embryotomy Safer.—DR. W. T. LUSK said he could hardly express his own views better than Dr. Garrigues had done. Success with Cæsarean section had not come to that point where we could say to our patients conscientiously that "this operation has its dangers, and embryotomy has its dangers, and they are so nearly equal that we would advise you to choose the former, whereby you will not only stand as good a chance of life yourself, but also of having a living child."

It was not true that Cæsarean section was attended with as little danger as craniotomy; it was an error to convey that impression to the profession at large. Of course, in large hospitals where the organization was perfect, some marvellous results had been obtained from Cæsarean section, but in the same hospitals there had been no mortality from embryotomy. As to his own experience with Cæsarean section, his first patient recovered easily, and he felt much encouraged; his second patient, although she had been in labor six days, recovered after a protracted illness; the third patient died, the cause of death being in the bowel; another patient died, though in good condition for three days after the operation. The autopsy revealed nothing. He thought we would do well to get eighty per cent. of recoveries from Cæsarean section, whereas after ordinary laparotomies we

could expect ninety-five per cent. of recoveries or more. Cæsarean section required more skilled assistants than craniotomy. Under these circumstances we could hardly go to families and enforce a rule to carry out Cæsarean section.

Weight of Native and German Children at Birth.—Dr. Garrigues said with regard to the statement that children here weighed at birth 7 to 7.5 pounds, while German statistics gave their weight as 6.5 to 7 pounds, would make them out of about equal weight, for we had to add about one-seventh to the German pound to convert it into the English equivalent. He had found on weighing a number of children born here of immigrants that their weight was about that of children of American parentage.

Embryotomy on the Living Fœtus Sometimes Indicated.—Dr. Charles Jewett sent a communication which was read by Dr. Grandin. He said he would perform embryotomy on the living fœtus because the safer operation under certain rare emergencies, such as the necessity for rapid termination of labor in the interests of the mother; where the mother was exhausted, or otherwise rendered unable to undergo an abdominal operation; where the conditions were not favorable for the child subsequently. In choosing between the two operations, account must be taken of the skill of the operator. The general practitioner unaccustomed to laparotomy had better undertake embryotomy.

Dr. Grandin said that statistics showing a mortality of twenty-five per cent. was sufficient to condemn Cæsarean section, but it must be remembered that in such cases the operation was not elective; it was resorted to only after the mother had been submitted to much shock and exhaustion from attempts at version, etc. He simply contended as yet for elective Cæsarean section in hospital practice. He thought that under circumstances of hospital practice it would soon show a mortality as low as ten, perhaps as low as five, per cent. As to the relative difficulty of Cæsarean section and embryotomy, he had found the former very easy, while the latter in his slight experience had proven very difficult. Then the chances of lacerations, septic poisoning, and even serious injuries as such, were marked in embryotomy.

Dr. C. A. Von Ramdohr, who arrived late, asked permission to reopen the discussion, and read the following:

1. Embryotomy of the living fœtus is justifiable, and its justifiability will hardly be disputed by any obstetrician, if the fœtus be (*a*) a hydrocephalic infant; (*b*) the head be engaged in a malposition (face mento-posterior; large head occipito-posterior); (*c*) the labor be of long duration, with either a suffering mother (pulse or temperature), or a weak child (difference of thirty beats during observation), where an attempt with forceps has proved in vain; (*d*) if after version the disproportion of fœtal head and maternal pelvis prove too great.

2. This discussion will, however, as four of the six announced speakers of the evening are connected with the Maternity Hospital, and are avowedly in favor of a relative indication of Cæsarean section, hinge on its justifiability, and here a different indication ought to be established between expert obstetricians and general practitioners.

(1) While a relative indication is permittedly justifiable, and may be imperative to the obstetric surgeon who can choose his time, his assistants, and has got all the appliances of a well-regulated hospital plus his laparotomy experience at his disposal;

(2) It ought to be declared malpractice for a general practitioner, unless furnished with all the requisites similar to the above, to put a relative indication for Cæsarean section as long as embryotomy is practically without danger to the mother, while Cæsarean section still represents a mortality of more than seven per cent., and as long as the fathers of modern Cæsarean section, Leopold and Sanger, have not agreed on the relative indication.

Stated Meeting, May 7, 1891.

Alfred L. Loomis, M.D., President, in the Chair.

Observations on the Use of Koch's Tuberculin in the Treatment of Pulmonary Tuberculosis.—Dr. Kinnicutt opened the discussion with a report of the results of treatment with tuberculin in cases of pulmonary and laryngeal tuberculosis in St. Luke's Hospital up to the present date. Forty two patients suffering from various forms of tuberculous disease had been inoculated under his personal supervision since December 10th. Of these 13 were cases of pulmonary tuberculosis, in 6 of which evidence of a tuberculous affection of the larynx also existed. The cases were divided into groups, viz.: 1. Cases in which notable improvement had occurred both in the pulmonary and general condition. 2. Cases in which either no improvement had occurred, or improvement in certain respects had been observed, and not in others. 3. Cases in which either distinct deterioration in the condition of the patient or progress of the disease accompanied the inoculations. The cases were described in detail and diagrams were exhibited, showing the changes in the laryngeal lesions, and also indicating numerically the number of bacilli found in the sputum in successive examinations during the period of treatment.

Five cases were included in the first group, all presenting on admission the physical signs of the first stage of pulmonary tuberculosis. Three of the patients had been discharged from hospital with cough and sputum practically absent, as well as bacilli. The improvement in the general condition and weight, and in the physical condition of the lung was notable in all. Two patients still remained in hospital under treatment. In these a similar improvement had occurred.

The second and third groups each embraced 4 cases. In one of the cases in the second group the laryngeal lesion had shown distinct improvement, in one the disease, similarly located, had progressed.

In the third group a striking example was given of the rapid development of a massive hepatization (catarrhal or caseous), followed by excavation, during and following the period of inoculations. The physical signs on admission, in this case, were those of the first stage of the disease. In a second case in this group, cardiac and renal disease were present before inoculation, and the discontinuance of the treatment was necessitated on account of these complications.

A few of the impressions which Dr. Kinnicutt had received from an experience of nearly five months in the treatment of various forms of tuberculosis with Koch's fluid, were summarized as follows:

General Impressions.—Tuberculin may be regarded as possessing marked elective affinities for tuberculous tissue. Its value in differential diagnosis must be considered as relative rather than positive. Doses of minimum strength, gradually increased and given at longer intervals than was originally advised, constitutes the safest and probably the most efficient method of its use.

Impressions of its Effects in the Treatment of Pulmonary Tuberculosis.—Beneficial effects from the use of tuberculin are apparently restricted to pulmonary disease in its early stages. In such forms of tuberculosis the most careful study of the individual, of the history and physical signs of disease previous to inoculation, does not permit an opinion of the probable nature or degree of reactions, or of the ultimate effect of treatment in any given case. The establishment of constitutional tolerance varies greatly in time in different individuals suffering from apparently similar lesions, and cannot be accepted as a basis for prognosis. Local reactions may continue to be developed under treatment, in the entire absence of constitutional effects as indicated by the temperature curve.

Tuberculin is apparently capable in certain exceptional cases even of incipient disease, of exciting pneumonic processes (catarrhal and caseous hepatization) of varying degrees of intensity. Whether such processes are due to

the conveyance into other parts of the lung of material affected by the fluid or by liberated bacilli, or are excited in some other manner, is uncertain. The production of hæmoptysis by tuberculin is comparatively rare. Its use necessitates the greatest watchfulness and entails much anxiety on the part of the physician.

In conclusion, it is my distinct impression that tuberculin is capable, in the early stage of pulmonary tuberculosis, of effecting a greater degree of improvement in the physical condition of the lung, and in more advanced disease, in many of the accompanying symptoms, than has been observed under any other method of purely medical treatment. Its sphere of greatest usefulness will probably be found in its combination with other methods of treatment.

The above impressions must be regarded as liable to modification with continued and more extended clinical study. They find expression only after the first enthusiasm excited by Koch's discovery has passed away, and are the impartial outcome of daily and laborious observations extending over a period of several months.

The discussion was continued by THE PRESIDENT, with a summary of the results obtained by him in Bellevue Hospital. Thirteen cases of pulmonary tuberculosis were treated by this method, 8 being in the stage of consolidation, 2 in the stage of consolidation with softening, and 3 in the stage of softening with excavation. The average age of the patients was twenty-eight years, and the average amount given at each injection, 1.9 milligr., the largest number of injections given in any one case being 77. The condition of every one of these patients was found at the end of the treatment to be improved, and the average gain in weight was 8½ pounds. In four of the cases, cough and expectoration almost entirely disappeared, and in all but two the number of bacilli in the sputum was diminished. In every case the physical signs showed, for from four to twelve days after the first injection, that the activity of the pathological processes in the lungs was greatly increased; but this would gradually subside, so that at the end of the third week, all signs of activity would have ceased, and the diseased areas would give indications of the arrest of the disease. Of the two cases in the second class, one died of disseminated tuberculosis; the other case gained 4½ pounds, the night-sweats became less frequent, the expectoration more abundant, and the bacilli more numerous. Four weeks after stopping the treatment, the physical signs indicated a large cavity at the original seat of the infiltration. In the four cases comprising the third class, the average age was thirty-five years, the average duration of the treatment eleven weeks, the average dose 0.7 milligr., and the average gain in weight, 9 pounds. The cough, the amount of daily expectoration, and the number of bacilli were not appreciably changed in most of these cases, but in all the pathological processes became much more active after the second injection. In two the moist sounds disappeared, and in one there was an extension of the disease.

His experience with this treatment had led him to conclude that tuberculin was an agent capable of exciting active changes in tubercular areas, the nature and extent of which depended upon the amount of fluid employed, and the frequency of the injections. If small doses, 0.1 milligr., were injected at long intervals the reaction would be slight, but the injections should never be repeated until the activity so induced in the tubercular areas has subsided, and then, if the patient be well nourished, it will often be found that there is an arrest of the phthisis. In this connection, he wished to state that he knew of no method which so effectually maintained the nutritive processes in these patients as the treatment with the pneumatic cabinet, as advocated by Dr. Quimby. Another point worthy of note was, that the number of bacilli in the sputum was not a reliable indication of the effects of the tuberculin on the phthisical process. He had found that the bacilli usually diminished in numbers, but never entirely disappeared, nor was it necessary that they should do so before a case could be considered as cured, for he had seen cases which had been cured by climatic treatment—in one instance as long as ten years—in which the bacilli could be found in the sputum, notwithstanding that the patients appeared to be in perfect health. While in the majority of cases he had observed an arrest of the phthisical process follow the treatment with tuberculin, it was too early yet to say whether or not this improvement was likely to be permanent. In a minority of the cases, the activity excited in the original tubercular area had been followed by a rapid development of new areas of disease, and in two instances by signs of general acute tubercular infection.

DR. H. N. HEINEMAN spoke of the observations which he had made in the Mt. Sinai Hospital, on twenty-two cases of pulmonary phthisis. Fifteen of these were in the second stage, and four presented cavities. Of the latter, one was markedly improved, one slightly, and two were not benefited by the treatment. In one case, giving a history of twenty-five years of cough, and presenting the physical signs of a chronic fibroid phthisis, after the treatment had been discontinued for several weeks the patient had for the first time a pulmonary hemorrhage, and these were repeated several times in the course of the next few weeks. In two other cases hemorrhages were brought on by small injections of the tuberculin. In the case referred to the patient presented himself with consolidation at the left apex, and a slight encapsulated pleurisy. During the treatment the pleurisy disappeared, leaving a solidified lung, but there was gradually developed over the entire left side a tuberculous process, which finally extended over the right side, notwithstanding that only small doses of tuberculin were employed. A continuance of the treatment, however, resulted in a partial subsidence of these symptoms, and the patient was ultimately discharged, decidedly improved in his general condition. In another case, having cavities and a small tuberculous testicle, the tuberculous process in the testicle became so active that four weeks later it was deemed necessary to resort to castration, and after the removal of the testicle scattered tubercles were found all through it. He did not think the number of bacilli was of much importance in determining the amount of improvement. He wished to call particular attention to the fact that the presence of any kidney or cardiac disease was a positive contra-indication to the use of tuberculin, for the albumin was always increased by such treatment, and in one fatal case he felt sure that the tuberculin was responsible for the development of a parenchymatous nephritis.

DR. E. L. TRUDEAU contributed a paper embodying the results of his observations with tuberculin in the Adirondack Sanitarium, which in his absence was read by Dr. Quimby. Eight cases had been treated in this sanitarium by tuberculin, combined with all the climatic, hygienic, and medicinal measures at command, *e.g.*, a residence in the bracing air of the Adirondacks, an out of-door life for eight or ten hours daily, irrespective of temperature or weather, careful feeding, and the administration of creasote in doses of from ten to eighteen drops, according to the digestion of the patient. Six of the cases also received treatment with the pneumatic cabinet for the purpose of expanding their lungs. The injections were usually given twice a week, and the dose was regulated so as to produce as slight a reaction as possible, and where this was marked the interval was lengthened and the dose diminished. After the initial reaction the dose was slowly increased, until from 18 to 100 milligr. were given without producing any appreciable symptoms. Four were cases of incipient phthisis, and four were more advanced and presented a daily rise of temperature. All had bacilli in the sputum. In one case, which was apparently cured, there had been several previous attacks of hæmoptysis, the sputum contained bacilli, and he had rapidly improved under the climatic treatment before undergoing treatment with tuberculin. One patient, a wo-

man with miliary tuberculosis at both apices, became much worse after the injections, small doses exciting violent and long-continued reaction, the temperature at one time reaching 104.5° F., and the pulse 160. The treatment in her case was therefore discontinued. The results may be summed up as follows: 1 apparently cured, 4 greatly improved, 2 unimproved, 1 apparently injured by the treatment. His experience with this treatment had taught him that it was not applicable to all cases, and that when rapidly pushed it always aggravated the disease. The decision as to its applicability depended not only upon the extent, but upon the type, of the disease, and especially upon the nutrition of the patient. The changes in the physical signs supported Koch's assumption as to the specific action of the fluid upon the phthisical process; but the tuberculin has no germicidal properties, and probably cannot give immunity against further infection. Koch evidently expected that it would secure temporary immunity, but Dr. Trudeau's own experiments on animals in this direction had proved uniformly unsuccessful. The success or failure of the treatment will depend upon our efforts to stimulate and support the nutrition of the patient.

Dr. C. E. Quimby prefaced his remarks by the statement that he had been attentively studying the effects of the treatment with the pneumatic cabinet for the past five years, and he had come to the conclusion that acute phthisis could be arrested in fifty per cent. of the cases, and that fifteen per cent. of the subacute cases would also be arrested, while the cases which had reached the third stage were always relieved. Bronchial hemorrhages are almost always arrested, and usually do not return, and in a series of two hundred cases he had seen only one in which hemorrhage occurred after the use of the cabinet, although many had had hemorrhages previous to its use.

He had treated six cases with tuberculin combined with the use of the pneumatic cabinet. The first and second had localized consolidation at the apex, the third and fourth were cases of diffused tuberculosis; the fifth showed diffuse infiltration with one or two areas prominently affected, and the sixth had extensive consolidation of the right lung, with pleurisy, cough, abundant sputum, and numerous bacilli. The diagnosis in every case but the last had been confirmed by Dr. A. L. Loomis. The pneumatic cabinet was employed to expand the lungs, and by the removal of catarrhal products to prepare them for the treatment. Inoculations with tuberculin were then practised, beginning with a dose of 1 milligr., and repeating the injections at intervals of about one week, the maximum dose being 2 milligr. In this way, specific processes were established in the lungs until the physical signs indicated active pulmonary changes. The pneumatic cabinet was then employed to favor absorption, until the physical signs showed a subsidence of the activity which had been produced. Antiseptic inhalations were also employed, and every endeavor made to stimulate the patient's general nutrition. The first case rapidly improved in general health and in the physical signs; the second improved in his general appearance, but the physical signs were aggravated; the third showed a lower percussion-note and stronger respiratory sounds, and the general nutrition was much improved; the fifth case had been previously subjected to the climatic treatment, but he derived as much benefit from the use of the pneumatic cabinet with tuberculin. In the sixth case, each injection increased the inflammatory changes in the lungs, but these were rapidly improved by the use of the cabinet. Bacilli were found in all the cases. Four out of six had hemorrhages, and strange to say, none of the patients developed a tolerance for the tuberculin. He thought tuberculin was chiefly indicated where the reparative processes were adynamic. The physical signs, and not the temperature, should be considered as the guide in the treatment by inoculations.

The general discussion was opened by Dr. A. Jacobi, who said that he had already spoken upon this subject before the State Medical Society in Albany, last February, and had then detailed a number of cases with the conclusions which he had reached, and these had been printed in the Medical Record. Children require relatively large doses, but it was advisable to begin with small doses in all cases, as the therapeutic effect does not depend upon the energy of the reaction, but on the contrary, was found to be most favorable in those cases in which there was very little rise of temperature. As an instance of the impossibility of predicting the effect of this remedy upon any given patient, the speaker related the following remarkable case: The patient was a lady about forty years of age, who had had tuberculosis for at least ten years. She had had large tubercular tumors in the abdominal cavity, and had expectorated more pus than he had seen in any case for many years, and she had also suffered from night-sweats. There were two large cavities in the lungs, and the sputum contained numerous bacilli. In the early part of the winter she had a pneumonia from which she recovered, but in December and in the early part of January she had some fever, although about January 10th, when the treatment with tuberculin was commenced, she was apparently in pretty fair condition. Her husband was a physician, and watched the case constantly. Beginning with 1 milligr., which gave no reaction, the dose was increased 1 milligr. each day until she received about 40 milligr., and yet no reaction was produced. The dose was then increased by 2 or 3 milligr. each day, until, about ten days ago, she was receiving about 350 milligr. daily. Although no reaction was produced, it was noticed that her fever would fall within an hour or so after each injection, and would remain so for eight or ten hours. At first the expectoration was more abundant, but it soon became more scanty, the number of bacilli was diminished, the night-sweats and fever disappeared, the patient gained in flesh, and her general condition was decidedly better. A few days ago, she had a slight fever from a fresh attack of bronchitis, but the cavities were decidedly smaller than before the treatment, and for weeks at a time no rhonchi are present.

In general, the treatment of surgical tuberculosis with tuberculin has been disappointing. Out of 16 cases of pulmonary tuberculosis, 4 were not improved, 5 were improved, 4 were much improved, 2 were cured, and 1 died. He thought that the best treatment in the future would be a combination of the climatic treatment with the careful use of tuberculin.

Dr. E. C. Wendt said that he had employed Koch's tuberculin in 38 cases—4 of surgical tuberculosis, 7 of phthisis, 22 cases of "strumous condition," 4 of ordinary bronchitis, and in 1 healthy person. It was interesting to note that in every case, the febrile reaction was obtained, and this would seem to invalidate Koch's claim for the diagnostic value of tuberculin. In the four surgical cases the patient became a little less anæmic and the local condition improved slightly, but the general condition was not materially affected. Six of the phthisical cases were in the first stage, and one in the second. All showed a decided gain in weight and their general condition was improved, but in not a single case were the physical signs improved. In the cases classified as strumous, and which consisted chiefly of children suffering from adenitis, the anæmia was improved, but there was no effect upon the glands, or upon the rude respiration. The initial dose had been invariably one-fourth of a milligramme.

Dr. S. Baruch's experience with this method of treatment embraced sixteen cases. The injections always produced marked changes in the physical signs, and on one or two occasions a decided pneumonia, which much to his surprise had disappeared within about forty-eight hours. In one case in the first stage of the disease, having cough, night-sweats, sputum, and bacilli, there was a gain of 14½ pounds, and a disappearance of the bacilli. The case was, however, improving before this treatment. Another patient, thirty-one years of age, also in the first stage, had had several hemorrhages, and at the time of be-

ginning the injections, on December 16, 1890, there was dulness at the apex, but no tubercle bacilli were present. The last injection, of 65 milligr. was given on April 15th, and produced no reaction, and there are no decided physical signs at present. He had gained twenty pounds at the time of his discharge, April 29th, as probably cured. A nurse in the hospital who developed cough and expectoration, and had slight hemorrhages with impaired resonance and fine moist rales, was found to have numerous tubercle bacilli in her sputum. She reacted to the first injection of 1 milligr. and to the twenty succeeding ones; but the last one, of 45 milligr., given on April 1st, produced little reaction; she had gained six pounds, there were no bacilli found, and she was discharged as probably cured. Dr. Baruch thought the tuberculin had some diagnostic value, and in cases of cavity was undoubtedly beneficial.

Dr. H. S. Stearns continued the discussion by referring to the results of two autopsies which had been made upon cases dying while under the treatment at Bellevue Hospital. In both cases, in addition to the old tubercular infiltration and fibroid condition, the lungs were filled with minute and recent miliary tubercles, probably as many as from four to eight nodules being present in any square centimetre. In both cases there was also general tubercular infiltration of the abdominal viscera.

In answer to a question from one of the fellows, who had noticed in the cases under his observation marked acceleration of the pulse, and a deepening of the respirations after the injections, Dr. Kinnicutt said, in closing the discussion, that although very accurate and complete records of his cases had been kept regarding the variations in the pulse, respirations, and temperature, he had not noticed this peculiarity.

The President said that he had seen one case in which there was a great acceleration of the pulse, and a slowing of the respirations, following each injection, so much so, that symptoms of collapse were produced by a dose of one-tenth of a milligr.

He thought the consensus of opinion was, that we had in tuberculin an agent powerful for good and evil, and one requiring greater care in its use, and more extensive experience, than any other agent which had been given to us for the treatment of this disease; but he thought it would take a permanent place in the treatment of pulmonary tuberculosis, and that by its aid we would be able to save many more lives.

Dr. W. H. Draper said that in view of the fact that an Advisory Committee, recently appointed by the Mayor to inquire into the condition of the street-cleaning department of this city, had, as a result of the most painstaking labor, produced a masterly report upon the defects of this department, he thought it advisable for the New York Academy of Medicine to signify its appreciation of the Committee's labors, and endeavor by its influence to carry on the work they had so ably begun. He, therefore, moved that the Academy pass resolutions expressing its hearty approval of the Committee's work, and its cordial endorsement of the suggestions contained in their report.

Dr. Jacobi, in seconding this motion, said that it seemed that, instead of teaching the poor immigrants how to be clean, we learned from them how to be dirty, and it was particularly unfortunate that most of the dirt accumulated in the most densely populated districts.

The resolutions were passed unanimously, and a copy was ordered to be sent to the Mayor and to each member of the Advisory Committee.

The Academy then adjourned.

Olive-oil in Gall-stones.—Professor Sée is a firm believer in the efficacy of olive-oil in the treatment of gall-stones. and explains its action by supposing that the fatty acids contained in it dissolve the cholesterine of the gall-stones.

Correspondence.

CHEAP DOCTORS.

To the Editor of the Medical Record.

Sir: In reply to an article in a recent issue of the Record, entitled "Cheap Doctors," permit me to say a few words in defence of the young physicians who have, by securing positions as examiners for industrial insurance companies, succeeded rapidly in building up substantial practices, even though the fee for each examination be only twenty-five cents.

The facts are these: There are several large and well-regulated insurance companies which insure men, women, and children for small amounts, *i.e.*, from twenty-five dollars to five hundred. Some have been established for years and have proved themselves reliable in every respect. So far as this is concerned, I consider such companies a God-send to many families in poor circumstances. Without them the Potter's Field would claim a much larger number than now.

These companies, to protect themselves from imposition and fraud from those who would, if they could, insure when in the last stages of disease, employ physicians (they are generally young men commencing practice) at twenty-five or fifty cents for each examination. This examination is short, sometimes merely an inspection of children, but thorough enough to give satisfaction to the company.

The young physician in this way gains an enviable experience. He soon learns to detect an abnormal condition, and he can give as much time to the examination as he pleases. He does not interfere with anyone's business; he does not prescribe, and if he does, he charges the regular fee or nothing. And, of course, he would not, as an honorable man, prescribe for anyone under the care of a professional brother.

A smart examiner can, at even twenty-five cents for each examination, earn over one hundred dollars per month (and I have known some to do better), and will then reject ten per cent. or more of unsafe risks. He will then have time left for study, or attention to such patients as he may have in charge. "A cobbler's wages" and advantages rank as paltry compared with his.

I can refer to several prosperous physicians who started in this way, and I should consider it good luck to him who secures such a position. If capable, he will soon be able to leave it.

George E. Hubbard, M.D.

THE GERMICIDAL POWER OF THE BLOOD.

To the Editor of the Medical Record.

Sir: In your recent editorial, bearing the above title, while discussing the experiments of Von Fodor concerning the action of certain chemicals and drugs upon this function of the blood, you say, "the statement that quinine lessens the germicidal power of the blood is absolutely untrue as regards the plasmodium of Laveran at least." To anticipate any further misconceptions which might possibly arise from an erroneous interpretation of this apparent conflict between his experiments and clinical experiences as alluded to by you, I will say the blood is a compound tissue possessing several and various attributes and components. Von Fodor only corroborates in the laboratory what has long been recognized and admitted in practice, that is, quinine exerts a marked inhibitory influence over the amœboid movements of the white blood-corpuscles and that this in turn lessens their phagocytic action and germicidal powers. In addition to this, quinine also lowers the germicidal properties of the blood-serum, which is known to be powerfully influential in guarding the organism against the invasion of disease-germs.

When we recall the fact that the plasmodium of Laveran occupies the red blood-corpuscles almost exclusively, and that it has little or no influence upon the other constituents of the blood, it may be readily seen that quinine, while lessening the two main factors of germicidal action, will at the same time exert a specific and independent destructive effect upon an organism which happens to be in the vicinity. This question is apparently explicable for these reasons and there is no real discrepancy in the two opinions. All of the investigations which have been undertaken in regard to the chemical and vital actions of the blood have been fruitful sources for scientific medicine. I for one am exceedingly interested in the possibilities and probabilities of the experiments of this character and only hope that they will be the means of finally solving some of the numerous and dark problems which continually beset us.

Respectfully,

J. Wellington Byers, M.D.

Charlotte, N. C., May 12, 1891.

HOW AMBITIOUS DOCTORS ABUSE MEDICAL CHARITY.

To the Editor of the Medical Record.

Sir: I read with much interest "F. R.'s" communication in the issue of your admirable journal of 28th ult., on the free dispensary question, and permit me to say a word in general reply—not in opposition, but favorably, to that broad humanitarian principle which underlies the giving of professional services and medicines free of charge to alleviate the suffering of mankind, but in opposition to the methods of distributing the charity and to the commercial motives of those members of our profession who bestir themselves so assiduously in promoting, organizing, and conducting this charity in the shape of so called free dispensaries and hospitals.

Let me speak first of the motives, not of the philanthropists who so generously and nobly endow these institutions, but of the designing and selfish members of our profession actively engaged in their management. It has been my observation, in a general practice of over twenty years among all classes of people, rich and poor, that, as a rule, those in charge of the dispensaries have been the beneficiaries of this well-intended philanthropy rather than the poor for whom it was designed.

But by whom and for whom are these institutions established? Let me cite a case. Dr. Dispenser (this name will serve my purpose of practical illustration) is a gentleman who stands well in his church, in social and political circles, a member of one of the so-called colleges or universities in some sort of capacity, with a practice probably meagre and incidental to the unimportant duties he performs in two or three hours each week in the lecture-room or at the clinic. He may have reached middle age, or he may be a fledgling just out of college in search of a practice, to secure which he is not willing to devote that care, attention, and faithful application so necessary for success. But whether old or young he is the same person. He decides to take up a specialty of the many. Perhaps he has devoted a little time and attention to one class of diseases, and in his practice of this character he may have started, on a small scale, a free dispensary which works fairly well in bringing him to the attention of the public, and in bringing to his office a number of patients whom he would not otherwise have secured, a proportion of whom he induces to pay for his medicines or his services, both if possible. This dispensary, crude as it is, is fairly successful, but somewhat expensive. If developed and expanded he sees in it a royal road to fortune. If he has not gotten so far as opening this small dispensary he has developed the idea in his commercial brain. In either event he is hampered by a lack of means. In providing these he makes his master-stroke. He appeals to charity, and he finds a gullable public. Now his position in the church and society, and his political connections stand him well in hand. He first unfolds his plans to one of his associates in the faculty, and spurred on by his encouraging counsel he admits the entire faculty into his plans, which are readily endorsed because they will possibly put one wheel revolving in another. But the faculty cannot provide the means. Charity is called upon to render that service. The first person along this line approached is the pastor of his church. The reverend gentleman becomes sincerely enthusiastic over the prospect of the Christian work to be accomplished. The pastor, in turn, interests his fold. Church socials and festivals, or some sort of church entertainment are given "for the benefit of the free dispensary," and as charitable affairs they appeal, and not unsuccessfully, to a generous public. Perhaps some wealthy member of the congregation, as has frequently occurred, becomes interested and in a sincere wish to aid humanity he contributes liberally, often lavishly.

Dr. Dispenser's plans are successful beyond his most sanguine expectations. He is delighted and revels in enthusiasm, which is shared by the prominent ladies and gentlemen who were instrumental in organizing the church festivals, and socials, and public concerts, and who have become the trustees, or visitors, or managers of the free dispensary, now fully equipped and "prepared to do business." One of the prominent members suggests the idea, most probably inculcated by the Doctor, of a hospital, where the poor can be housed, nursed, and otherwise cared for, as well as receive medicine and surgical attention. Dr. Dispenser is naturally delighted with the idea when publicly promulgated, and the work of establishing the hospital begins. He finds that the aid derived through church and social influences would be inadequate alone to either build, equip, or maintain the hospital. Not daunted, however, he casts his eye upon the city's treasury and summons to his aid his political connections. He visits the councilman of his ward, generally a professional politician, whose aid, it seems, is available whenever the question of the expenditure of the public funds arises. Then all of the considerable influences of the various boards of visitors, managers, trustees, etc., are brought to bear, in connection with that of Dr. Dispenser, upon the City Council, and an ordinance is passed appropriating a good sized sum to the "Church Hospital and Free Dispensary" (the hospital now overshadows the free dispensary). A building site may be thrown in, as has happened. All of this is done on the understanding that a certain number of free beds in the hospital are to be at the disposal of the city. The good work of the hospital and free dispensary is chronicled abroad, first in reports in the medical journals, which are reproduced in pamphlet form for free distribution, then in the church and public press, all of which free advertising of course inures to the benefit of Dr. Dispenser, who, by the way, in the meantime has been elected a full-fledged professor in his particular specialty in one of the so-called colleges. Although professedly a great stickler for medical ethics, he does not hesitate to resort to this method of advertising, and he modestly receives the benefits derived.

Now the natural effect of these practices is to so enlarge the usefulness of the hospital and free dispensary generally (and Professor Dispenser's outside practice incidentally), that the capacity of the hospital must be enlarged proportionately. Whence shall come this needed aid? The church cannot afford to increase its already large contribution; the philanthropist has done his part nobly; the city council cannot be reasonably expected to increase its annual appropriation. Although all of his home resources are exhausted he is not at a loss for a new and even broader field of operation. He applies to the State legislature. The Professor's reputation has already preceded his application, having been thoroughly advertised through the medium of his charities. If he meets with any opposition in carrying through his appro-

priations the influences of the active and honorary boards above referred to, together with other factors best known to the Professor, are brought to bear simultaneously upon the legislature in general and upon the rural representative in particular. Delegations, composed of a [illegible]

CAN THE TUBERCULE BACILLUS BE DESTROYED BY THE PNEUMOCOCCUS?

To the Editor of the Medical Record.

Sir: Reading Dr. Moor's article in the Record of May 23d, on the theoretically ideal remedy for pulmonary tuberculosis, called to my mind a communication from Dr. N. McCabe, in the Record of January 17, 1891, in which he reports a case of acute tuberculosis apparently cured by an attack of pneumonia.

Dr. Moor, supported by clinical and post-mortem evidences, claims a decided antagonism between the bacillus of tuberculosis and pneumococcus, either chemical or dynamical. The question has presented itself to me, Can the tubercle bacillus be destroyed or rendered harmless by the artificial introduction of the pneumococcus? Experiments on rabbits or guinea-pigs ought to be able to determine that.

To show the apparent cure of one suppurating disease by the supervention of another acute disease, I will refer to two cases. About two years ago Dr. Emerson presented at a clinic at the Manhattan Eye and Ear Hospital a patient who had suffered from extensive mastoid disease, following disease of the middle ear, which baffled all treatment, and nearly destroyed the patient's life, but who completely recovered from the mastoid disease after an attack of erysipelas of the face. Ten years ago I had suppurating lymphatics of the neck, which seriously undermined my health (several of my near relatives died of phthisis and scrofula), and which persisted, in spite of local and general treatment, for upward of six months. I also had erysipelas of the face, and to my astonishment but great satisfaction my troubles ceased with the disappearance of the erysipelas, and I have had no return of the glandular trouble. Are these mere coincidences, or did the bacillus of erysipelas destroy the other microbe? I believe the latter, and am therefore led to suppose that the pneumococcus may be capable of destroying the bacillus of tuberculosis.

I have neither the means nor the ability to carry on the experiment; if others have tried and failed, they have kept it to themselves, as far as I know, and if they succeeded they have not told of it in the Record. Am I unreasonable in thinking that there may be something in this?

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from May 31, 1891, to June 6, 1891.

Waters, William E., Major and Surgeon. Granted leave of absence for twenty days. S. O. 122, par. 6, A. G. O., Washington, D. C., May 28, 1891.

Kean, Jefferson R., Captain and Assistant Surgeon. By direction of the Secretary of War, is assigned to temporary duty at Fort Myer, Va., until the return of Major Robert H. White, Surgeon, to duty at that post. S. O. 122, par. 8, A. G. O., Washington, D. C., May 28, 1891.

Carter, Edward C., Captain and Assistant Surgeon. Will proceed without delay to Fort Canby, Wash., and report to the commanding officer for temporary duty, relieving Major John D. Hall, Surgeon, who will proceed to Fort Sherman, for duty as Post Surgeon. S. O. 74, par. 1, Department of the Colorado, May 22, 1891.

Kean, Jefferson R., Captain and Assistant Surgeon. Granted leave of absence for one month, to take effect after the return of Major Robert H. White, Surgeon, to duty at Fort Myer, Va. S. O. 123, par. 1, A. G. O., Washington, D. C., May 29, 1891.

Huntington, David L., Major and Surgeon. With approval of the Secretary of War, granted leave of absence for three months, to take effect on or about June 15, 1891. S. O. 124, par. 2, A. G. O., Washington, D. C., June 1, 1891.

Birmingham, Henry P., Captain and Assistant Surgeon. By direction of the Secretary of War, the extension of leave of absence, on account of sickness, granted in S. O. 108, May 12, 1891, from this office, is further extended to June 21, 1891, on surgeon's certificate of disability. S. O. 125, par. 6, A. G. O., Washington, D. C., June 2, 1891.

Hall, John D., Major and Surgeon. By direction of the Secretary of War, par. 1, S. O. 74, May 22, 1891, Department of the Columbia, transferring him from Fort Canby, Wash., to Fort Sherman, Idaho, is confirmed. S. O. 126, par. 4, A. G. O., Washington, D. C., June 3, 1891.

Hoff, Van R., Captain and Assistant Surgeon. By direction of the Secretary of War, is relieved from duty as a member of the Board of Medical Officers to which he was assigned by par. 6, S. O. 78, April 7, 1891, from this office, and will, upon the completion of the duties assigned him by par. 6, S. O. 110, May 14, 1891, from this office, return to his proper station, Fort Riley, Kan. S. O. 126, par. 11, A. G. O., Washington, D. C., June 3, 1891.

Official List of Changes in the Medical Corps of the United States Navy for the week ending June 6, 1891.

Gravatt, C. U., Surgeon. Detached from Naval Hospital, Yokohama, Japan, and ordered home.

Rogers, Franklin, Surgeon. Detached from special duty at Norfolk, Va., and ordered to Yokohama Hospital.

A Hospital for Infectious Diseases in Turin.—The King of Italy gave 160,000 lire ($32,000) on his last birthday to the city of Turin to assist in the erection of a hospital for contagious diseases.

An Early Proof of the Value of Vaccination.—A correspondent of the *British Medical Journal* sends to it the following extract from a French newspaper of October 3, 1804: "Six black children, the first who had ever been vaccinated at the island of Réunion, and from whom 5,000 people were vaccinated, were shipped on board the vessel Jeune Caroline, bound for one of the Seychelles Islands to perform quarantine for small-pox. The six children were three months on board the ship, eating, drinking, and sleeping with the sick; during the time of quarantine they were inoculated with the virus taken from the pustules of the diseased passengers, by large incisions made on both arms. From the report made at the time and communicated to the Central Society of Vaccine by the Minister of the Home Department, it was found that, although these six children had slept under the same blankets, and in contact with the pustules of the sick, eating and drinking out of the same vessels, and having been inoculated with pus from the patients who ultimately died of the disease, they were all preserved from the contagion, and were during the whole time in perfect health. The proof and counter-proof is one of the most severe tests ever performed, and ought to have a marked place in the history of vaccination. The fact of six children having lived in perfect health on board a small ship infected with small-pox, having on board twenty blacks with confluent small-pox—six of whom died—twenty to twenty-five others with dry crusts all over the body, with seven deaths before their arrival at the quarantine station, all packed in a small space between decks, is perhaps the most crucial test ever witnessed of preservation by vaccination."

Dr. O'Dwyer's Views on Intubation.—At the recent session of the Missouri Valley Medical Society, at Omaha, Dr. Inches, of Scribner, Neb., read a letter from his former classmate, Dr. O'Dwyer, regarding the operation of intubation. In this letter Dr. O'Dwyer gives the views he at present entertains regarding the operation of which he is the father. He states that intubation, like everything new, has been much abused and that it is a difficult operation to perform because of the celerity with which it must be done. The necessary skill can only be acquired by a great amount of practice on the cadaver. Unless this be done much suffering will be caused and many lives sacrificed. For these reasons Dr. O'Dwyer is of the opinion that the operation should not be attempted by those inexperienced in its technique, and believes that one intubationist in a city of fifty thousand is sufficient. Regarding the indications for the operation, Dr. O'Dwyer says that should death be impending from obstruction in the larynx, and should one competent to perform intubation be at hand, it should be done, otherwise tracheotomy is to be preferred as the safer of the two. He further stated that intubation will accomplish all that tracheotomy will and a great deal more, but that tracheotomy may be called for after intubation has failed should loose membrane exist in the lower part of the trachea. As a primary operation in croup when an intubationist is at hand Dr. O'Dwyer regards tracheotomy as absolutely unjustifi-

Improved Ship Sanitation.—Charles Henry Leet, Late Surgeon-Major of the Royal Engineers (England), is making a commendable fight for better ship sanitation. He claims that in the great majority of English ships it is wofully bad, and he knows whereof he speaks, as he served eight years as medical officer in six first-class passenger steamship companies. The British laws make it compulsory for the ship surgeon to report on the sanitary condition of his vessel at the end of each voyage, but owing to intimidation by ship-owners it is alleged that the law is a dead letter. In many companies an adverse report costs the surgeon his position. Dr. Leet proposes that the Seamen's Union take the matter in hand, that the seamen be instructed in the principles of hygiene, and that they make reports of unhealthy forecastles and deckhouses, poor ventilation, etc. This would insure a survey by competent authority and many of the existing abuses would be corrected. The sailor's stock in trade is his health and any reform looking to the correction of anything that endangers it is a good one.

THE PHONOGRAPH AND THE MICRO-GRAPHOPHONE AS AN ASSISTANT TO MEDICAL AND OTHER SCIENCES.[1]

BY J. MOUNT BLEYER, M.D.,

NEW YORK.

MR. PRESIDENT AND GENTLEMEN: I bring before you the results of some studies I have made in regard to the phonograph and the micro-graphophone. My object in the pursuance of these studies was to ascertain exactly the practical value of these inventions in regard to medical and other sciences. The results have been most gratifying to me, and to-night I am able to demonstrate to you such practical fruits as will undoubtedly be of great service.

Before entering upon the reading of my paper I wish to say a few words concerning the inventor of this machine. Just ten years ago, a young man entered the office of one of our leading scientific journals and placed before its editors a small and very simple machine, about which few preliminary remarks were offered. The visitor, without any ceremony whatever, turned the crank, and to the astonishment of all present the machine said "Good morning!" "How do you do?" "How do you like the phonograph?" And so the machine, speaking for itself, made known the fact that it was that wonderful instrument, the phonograph, about which much had been said and written, although little was in reality known. That young man was Thomas A. Edison. The machine was his latest invention, and the editors and employees of the scientific journal before mentioned composed the first audience to which it addressed itself.

The invention was novel, original, and apparently destined to find immediate application to hundreds of requirements; though at that time it was scarcely more than a scientific curiosity or an amusing toy. Mr. Edison, however, recognized the fact that it contained the elements of a successful speaking machine, and thoroughly believed that it was destined to become far more useful than curious or amusing. He contended that it would be a faithful stenographer, reproducing not only the words of the speaker but the quality and inflections of his voice, and that letters, instead of being written, might hereafter be spoken. He believed that the words of great statesmen and divines might be handed down to future generations by its means, and that the voices of the world's primadonnas might be stored away and preserved, so that long after their decease the magic of their tones would still remain to charm the world's ear.

These and many other things were expected of the phonograph. It was, however, doomed to a period of silence. It remained a toy and nothing more until a few months since, when it was made known to the public that the ideal phonograph had been constructed; that it was unmistakably a good speaker and excellent imitator, and that the machine which people long before believed had reached its full power, had now been refined and improved until it was capable of faithfully reproducing every word, syllable, vowel, consonant, aspirant or, indeed, sounds of any kind.

The phonograph and the micro-graphophone stand here before you, and before I come to the end of my paper I intend to illustrate by their aid the points which I wish to impress upon you. The power of these impressions I leave to your judgment.

It is not my aim in this paper to go into details concerning the construction of these machines, with the exception of a few necessary explanations without which this discussion would prove lengthy and uninteresting.

Most of my auditors have heard the phonograph and understand the principles of its construction. The simple foundation principle of the perfected phonograph, consists in the cutting of minute impressions upon the surface of a small wax cylinder by means of a tiny cutting instrument, actuated by sound-waves and returning in these same minute impressions or punctures; afterward setting in vibration a small diaphragm attached to a delicate needle-point that delves in and out of the minute impressions with inconceivable rapidity, as the wax cylinder is revolved beneath the needle-point, with the latter slightly resting upon the waxen surface.

A curious feature of the modern phonograph is the difference made in the key of the voice by an increase or decrease in the velocity of the cylinder. If the latter is turned as fast in transmitting the voice as it is in receiving, the sound is reproduced with almost mathematical fidelity. If, however, the cylinder is turned more slowly, the voice is reproduced in a much lower tone. So, on the other hand, if the mechanism is moved more rapidly the voice is reproduced in a much higher key. This curious fact enables a person to hear himself speak as if he had been endowed with different vocal organs. A contralto, for example, who sings a song into the apparatus in her usual style may hear it reproduced as she gave it, or by changing the speed of the motor, as a soprano, mezzo-soprano, high treble; or, on the other hand, as a baritone, basso, or even basso profundo. Of course, it must be remembered that there is a change in the time corresponding with the change in the key. The high treble sings so rapidly as to grate upon the ear, while on the other side, the basso vocalizes so slowly as to suggest somnolent fatigue. Strange to say, the quality of voice which the French call timbre remains unchanged, no matter what tone is employed. Even the little peculiarities which distinguish each individual remain the same under all circumstances. It seems impossible, but it is a fact, that the phonograph permits us to almost photograph the voice. The minute indentations on the cylinder can be photographed and enlarged, put on metal, and then printed. Just as each man differs from every other man in face, physique, signature, habits, and modes of thought, so does he differ also from an acoustic standpoint. A photograph of a speech prepared in the manner mentioned would be as accurate a method of indentifying a man as his photograph itself.

The study of the mechanical construction of the phonograph and the micro graphophone will not occupy for long the attention of one who has the slightest mechanical turn of mind. It is very necessary that the operator should understand the workings of the delicately constructed diaphragm and recording and reproducing needles. The resetting of such needles and diaphragms when out of repair, and the keeping of the machine in proper running order, these few points anyone can in a few hours master with little difficulty. As, for instance, in taking a record an accident may easily happen to any part of the machine, one must at all times be ready to repair, or if

[1] Read and demonstrated before the New York Medical Association, April 20, 1891.

necessary replace, any part of it, by so doing avoiding inconveniences and the frequent loss of valuable records. I advance these hints in order not only to suggest, but to prove the advantages of this machine for practical purposes. Everything about the machine is duplicable, and may be replaced at once by oneself or by notifying the company. This company has a corps of regular inspectors whose duty it is to inspect and correct every machine in use. But, as I mentioned before, it is far better to master the construction for oneself and so save valuable time and frequent losses.

I now come to the subject proper, and to discuss it thoroughly must classify it under the heads of its various uses.

The Value of the Phonograph in Medical Sciences.—For some years I have occupied myself in studying the uses to which this machine may be put in the medical as well as in other sciences, and I can say that already. in the present stage of its construction, it can be made to record many of the symptoms usual in diseases of the respiratory tract in both normal and abnormal states. For instance, the voice of singers, when in good voice, may be recorded and kept for comparison in case of any ailment, making the normal record a standard. Phonograms of tenors, baritones, and bassos may be preserved, the voices studied as to the different shades of tone and quality, and be found of value in clinical as well as in other demonstrations.

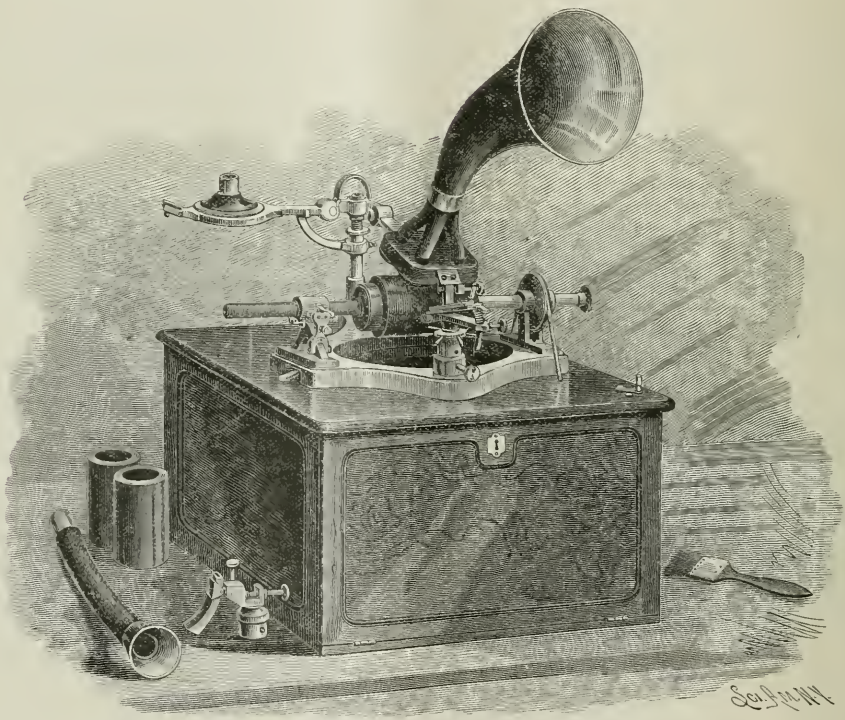

Fig. 1.—Micro-graphophone.

In Didactic Teaching.—Good records of specimen patients illustrating a certain cough—such as the whoop of whooping-cough, asthmatic cough, bronchitis, stenosis of the larynx, and in croup and diphtheria—would be of great benefit, particularly in cases of diphtheria and croup where the stenosis is marked. A standard for operation might be selected, and the students, listening through a cylinder, receive the impression therefrom as to about the correct time when operative interference becomes necessary, taking the normal breathing as a contrast to that of stenosis. With the aid of such practical demonstration in the lecture-rooms of our colleges, I am certain that our students would gain more from one lecture than from two dozen of the ordinary and prevailing ones. Taking into consideration the fact that, only too frequently, when we wish to demonstrate some particular clinical case to our students with a view to illustrating certain points of interest therein, a proper subject usually cannot be found, and words most feebly take the place of facts. But words are easily forgotten, while an illustrated fact becomes indelibly written upon the brain. Now, on the contrary, if good records of clinical cases in one's private or hospital experience be taken and kept, then living examples are always in readiness, and may be presented in the various stages of the case.

No didactic lecture need be given without illustrative effects and consequent benefit to the student, while with such assistance the student will catch clearly and readily the meaning of scientific technicalities used in connection with certain symptoms, etc.

Cabinets may be arranged as laboratories in which all kinds of records may be preserved, representing the different stages of diseased conditions of the respiratory tract—say, for example, hysterical cries, the shrieks of raving maniacs, etc. To such phonographic libraries many interesting features might be added too numerous to mention here.

The phonograph may also be applied as a corrector to restricted speech in children and grown persons, while a still further use for it is advanced by Dr. Sturges, who employs it as an acumeter of hearing.

In other sciences, for instance, the teaching of languages, the phonograph becomes a tutor—a tutor, moreover, with a correct pronunciation.

A practical application of the phonograph has been suggested by Dr. Richard S. Rosenthal, the well-known

author of the Meisterschaft system, which is already productive of very satisfactory results. That is, the instruction in the pronunciation of foreign languages. The difficulty of learning a foreign language without association and personal intercourse with one who is a native, is well known to all who have endeavored to acquire such a knowledge by self-instruction. I am told that a number of Dr. Rosenthal's pupils are already engaged in this, the ideal way of mastering foreign languages. The pupils are supplied with books and prepared cylinders to match. The method of study is to train the eye and the ear at the same time, and a pupil with his lesson on the cylinder can, by hearing it over and over again, master the pronunciation perfectly, while his eye at the same time follows the printed text which makes him familiar with the spelling and appearance of the words.

As an automatic teacher of elocution, this novel idea has been brought into actual execution, and is at the present time being practised by a number of actors and actresses. The example was set by Clara Morris, who obtained a phonograph and used it to ascertain exactly how her speech sounded. She had become convinced that no speaker could catch the tones of his or her own voice exactly as others did. It occurred to her that by speaking into a phonograph she could receive in return a correct idea of her vocal expression. Her plan succeeded admirably. She recited doubtful portions of her rôles into the machine, and had to repeat them again and again for her criticism. The story of Miss Morris's experiment leaked out, and now there can be counted at least a dozen players who, in studying their parts for next season, are calling this machine to assist them in their efforts toward correct vocalization.

Recently Mr. Godofsky, the great Russian pianist who is here on a concert tour, while listening to my phonograph reproduce several compositions he had played for us, conceived the idea of using the machine to register the inspirations that might come to him and escape before they could be transferred to paper; thus receiving them in their entirety and preserving them for future use. He is delighted with his experiment, and finds it of great benefit to him.

A very interesting and popular use of the phonograph will be the preservation and distribution of songs by great singers, speeches and sermons, the words of great men and women, the music of many parts. Through its power of reproducing the voices of animals it may also become an aid in the study of natural history. Mr. Edison has made some experiments by which he intends to determine, if possible, if certain insects emit sounds which are inaudible to the human ear because of the rapidity of the vibrations of the sound-waves. He places them for a few moments with the phonograph revolving at a very high speed, and then, with a greatly reduced speed, endeavors to reproduce any sound that may be recorded.

Its uses cannot be too greatly dilated upon. For vocal teaching, dictations, correspondence, for civil and military orders, for reading to the sick in hospitals, it is invaluable. In the composing room it will be of use to the compositor, who may set his type directly from the dictation of the machine without the necessity of copy. These are only a few of its possibilities, various other ones might be mentioned did time permit.

Mr. Edison informs us that the whole of "Nicholas Nickleby" can be recorded upon four cylinders each four inches in diameter and eight inches long, so that one of these instruments in a private circle or in a hospital could be made to read a book to a number of persons. The multiple ear-piece by which this is accomplished is shown in Fig. 1.

The little wax cylinders upon which the record is made, are provided with a rigid backing, while the cylinders themselves are made in different lengths, the shortest one inch long with a capacity for two hundred words, the next in size four hundred words, and so on. These cylinders are very light, and a mailing-case has been devised which will admit of mailing them as readily as letters are now mailed. The recipient of the cylinder has only to place it on his own phonograph and listen to the phonogram, in which he will discern not only the meaning conveyed by the words, but also the very tones and expressions of the sender; which will, of course, add materially to the interpretation of the message and convey more forcibly its meaning.

Additional Hints.—For the taking of clear records of singers, elocutionists, music, etc., an empty room with good acoustics is absolutely essential. Also clean-shaved cylinders and the correct motor speed of the phonograph.

The proper distance of the person recording from the funnel of the phonograph must also be taken into consideration. My advice to all who make or take records is to keep the phonograph in perfect condition. No set rules can be given as to how to take records, this is a matter of good judgment, and lies entirely with the operator. Making musical records is like taking photographs, you get your results according to the skill employed. Experience teaches the rest.

The micro-graphophone is the invention of Liet G. Bettini. In the construction of his talking machine his object was to record articulate speech and other sounds, and reproduce them more distinctly, more naturally, and with greater amplitude, in order to obviate the necessity of hearing-tubes, and to be sure always of having a good record made and a good reproduction. His experiments have shown him that to attain these ends there must be changes made, as much in the recording device as in the reproducer. In his recorder, instead of attaching the recording knife to one point in the centre of the diaphragm, as in other talking machines, he uses a device (which he calls a spider, because it looks like one) to which a knife is attached in the centre, on one side, with branches or legs of different lengths attached to several points of the diaphragm on the adverse side.

A diaphragm, made to vibrate by sound-waves, vibrates over its entire surface, but with different degrees of vibration at different points. Tyndall, and other masters of the science of sound, show a vibrating diaphragm or body covered with dead points, called knots, points where the vibrations are indistinct or dead. If Tyndall and other scientists are correct (which he thinks will not be disputed), if a knife is attached to an only point on the diaphragm, the point selected may sometimes be dead or nearly dead, and consequently the vibrations cannot be correctly recorded. Such a diaphragm may sometimes make a very good record, and sometimes an altogether unsatisfactory one.

Suppose a spider attached to a vibratory body by many legs of different lengths, six or eight or more. Two or three of the points of attachment may sometimes be dead points, and unable to transmit vibrations, but by the others the knife will receive all that is necessary to make a good record.

The spider gives to his device other advantages. It gives more strength to the knife in making a record, as this strength is concentrated from several points, whereas in other machines it has but one source; further, it gives to the knife great steadiness, which he considers most important; and, further yet, a great advantage is that in his device, not only are all the tones recorded, but also the half-tones, the over-tones, and the intermediate tones. This he is able to demonstrate by mathematical figures.

To recapitulate: In recording articulate speech or other sounds, he takes the vibrations from the body or diaphragm at several points or places, and communicates them by independent conductors to a common point or place, causing the record to be made from this common point or place; and the record thus obtained is a perfect one. The Bettini machine has two kinds of reproducers.

In the reproducing device, instead of a small diaphragm made to vibrate by means of a needle attached in the

centre by a point, he has a larger diaphragm divided into several smaller divisions, three, four, five, or more, and the vibrations are communicated to these different diaphragms by a spider, having in the centre, on one side, a reproducing needle, and on the adverse side legs extending to the centre of each of the smaller divisions.

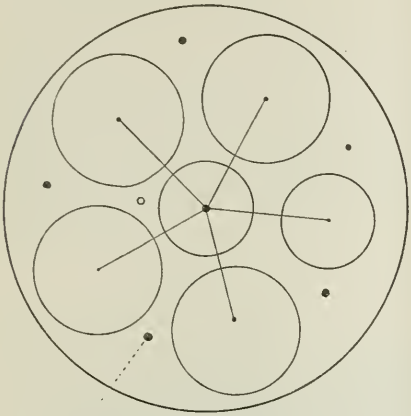

FIG. 2.—Old Reproducer Formerly in Use. *A*, points under different tension.

Thus the method of reproducing articulate or other sound or sounds consists in causing a record of vibrations to act at a single point or place, and from this point or place to communicate vibrations by independent conductors to the several diaphragms. But this is not the only important end attained by this device. It is very desirable to be able to reproduce the exact natural pitch or tone of the voice or other sound. As with a number of tuning-forks, some of which will gather vibrations where others will not, one diaphragm, also, will take certain vibrations which others are unable to take on account of tensions, dimensions, and other physical conditions of the same diaphragm.

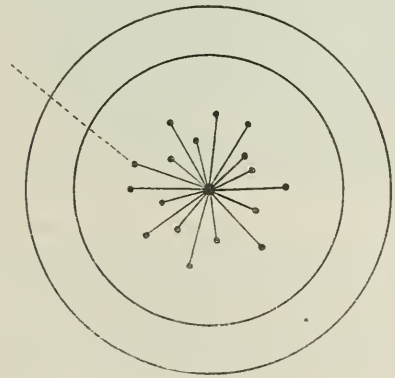

FIG. 3. -Reproducer now in Use. *A*, points under different tension.

In his device, having a diaphragm divided into several divisions of different tensions, or dimensions, or other different physical conditions, he succeeds in giving a more natural reproduction both in volume and in pitch, because in case unusual vibrations should be reproduced, he has always one or more diaphragms that will sympathize with these vibrations, and no vibration is ever lost.

It is very easily seen that a single diaphragm, which is made to vibrate in the centre by a needle attached at one point, will give a minimum result, because the diaphragm only vibrates, with appreciable results for our ears, in a small part of the centre.

A reproducing diaphragm with a spider attached by its legs at several points, will vibrate over more of its surface; the result of several diaphragms vibrating at the same time will naturally give more amplitude to the reproduction.

With such devices, the micro-graphophone gives a repro-

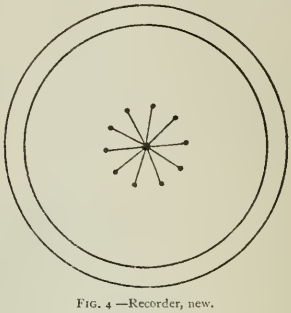

FIG. 4 —Recorder, new.

duction for which no hearing-tubes are necessary. The voice and all other sounds are always emitted into the room still retaining all their natural qualities, and each completely distinct and distinguishable.

The phonograms demonstrated: The cry of a baby of three months; the whoop of whooping-cough; complete aphonia, due to chronic laryngitis; acute laryngitis —the cough illustrating the characteristic stridulous metallic sound in the early stages; nasal stenosis and nasal twang; hoarseness; an asthmatic patient; the cough of phthisis; stuttering; imperfect speech; sneezing; normal breathing contrasted with abnormal; the stenosis of croup; languages — correct pronunciation of French, German, English, Russian, Italian; elocution and acting; singing by singers of the Metropolitan Opera House, etc.

A CASE OF LOOSE BODY IN THE KNEE-JOINT,

WITH DESCRIPTION OF THEORIES OF ORIGIN, PATHOLOGY, SYMPTOMS, AND TREATMENT OF LOOSE BODIES IN JOINTS.[1]

BY M. S. KAKELES, M.D.,

SURGEON MOUNT SINAI HOSPITAL, OUT-DOOR DEPARTMENT.

LAST September a young man, aged about twenty-one, presented himself to me with the following history: About eight weeks previous, while dancing, he fell and injured his left knee. He arose with severe pain over the region hurt, and immediately returned to his home. The next day he found the joint considerably swollen and painful, which necessitated him seeking medical advice. From the description given me I inferred he had been treated for an acute synovitis, which, he said, ran its course in two or three weeks. His family physician discharged him, apparently cured, after this time, with the exception of a slightly distended joint. This gave him no further trouble whatsoever until about nine weeks later, when he accidentally noticed something floating around in his knee. He again consulted several physicians, all of whom diagnosed a loose body, and advised its removal. On examining the knee when he presented himself, it was found slightly distended, and a flat, oblong body, about $4\frac{1}{2}$ ctm. long by 3 ctm. in breadth, could be easily detected floating freely about in its cavity. Its thickness seemed about $\frac{3}{4}$ of a ctm. So movable was it that by the simplest manipulation it could be placed in any position on either side

[1] Read before the Metropolitan Medical Society, January 21, 1891

of the patella, beneath the tendinous attachments of the extensors of the thigh. It could be turned upon itself around its longest diameter, and, in fact, was the most freely movable body of its size I had ever seen in a joint. It would occasionally, when the knee was moderately flexed, be caught between the articular surfaces of the femur and tibia, and cause the patient considerable pain. All these movements of this body naturally could only be performed when the leg was most extended. He was not contented with the advice his several physicians had given him, and consulted me for another remedy than that which would necessitate the opening of his joint and the risk of probably confining him to his bed for several weeks. I could not advise him differently, and finally, after much persuasion, got his consent to an operation. The usual necessary precautions attending operative opening of so important a joint were followed with strictest details. The joint was opened directly upon the body, when it shot out with perfect ease. The skin was sutured, an antiseptic dressing applied, the leg and thigh placed upon a splint, and after eight days the first dressing was removed and the wound found to have united primarily without the slightest reaction. He was advised to wear a light flannel bandage around his knee, as a support, for some little time, and was discharged perfectly cured.

There has been a diversity of opinion as regards the nature, structure, and origin of these foreign bodies, and as the specimen removed is such an excellent example of the character of a kind to be described, namely, of a piece of the articular cartilage of the end of the femur exfoliated, I thought it of sufficient interest to take as my subject for this paper, the "Theories of Origin, Pathology, Symptoms, and Treatment of Loose Bodies in Joints."

These bodies have been known to exist in joint-cavities ever since the time that Ambrose Paré, in 1558, removed a cartilaginous nodule from the knee of a patient, and until further investigations concerning their anatomical structure were made, all loose bodies in joint-cavities were called loose cartilages. Inasmuch as these foreign bodies may be osseous, fibrous, lipomatous, cartilaginous, or of a mixed character, such as fibro-cartilaginous, or even foreign substances introduced by accident into a joint, one readily appreciates that the title, loose cartilages was a misnomer. These foreign bodies vary in size, shape, and number. They are found in almost all the joints; but, strange to say, ninety per cent. have their origin in the knee. Why this predilection is not quite satisfactorily explained, unless it be that the synovial membrane in this cavity has more reduplications than in any other joint. The elbow is next in frequency, while the hip and temporo-maxillary joints are rarely the seat of origin.

They vary in size from those scarcely perceptible to those 4 or 5 ctm. in diameter. They may be either single or multiple. (A case is recorded where four hundred were removed from a single joint.)

Their shapes are diverse, frequently circular plates, either biconvex, or biconcave, or concavo-convex. Oval, oblong, spheroidal, and pyriform bodies also have been found.

Naturally these different shapes must be due to the manner of their origin and growth. According to their anatomical nature they may be divided into different classes.

The first are not very common, namely, those formed by organization of a clot. This can only arise from an injury whereby blood is effused into a joint-cavity. The blood may be rich in fibrin, and the clot may remain adherent to the parts which excreted it and organize there into a fibrous body; or, again, the effused fluid in an acute synovitis may also be rich in fibrin and may organize and form small tufts or bodies which have come to be known as melon-seed bodies adhering to the membrane, similar to the fibrinous exudates on mucous or serous surfaces. From the blood effused in the incised wound made for the removal of a body in a joint the organization of the blood-clots may account for the rapid appearance of numerous loose bodies.

This theory may be denied by some, but we have every reason to believe that organization of blood-clots may take place just as well inside a joint as in a wound made on the surface of the body.

The second class are found in persons who have the dyscrasia where there is a tendency to deposits of osteophytes around the joints, namely, those suffering from osteo-arthritis deformans. Those deposits lying near the synovial membrane are liable to protrude into it, as will be described.

The third class are real tumors or outgrowths from the cartilage, called ecchondrosis; these are very rare.

In the fourth class, rheumatic diathesis often is a cause of certain of these bodies, since they have been found in persons of this dyscrasia, and it is therefore reasonable to suppose that it plays an important factor as a cause; when such is the case they are usually multiple, and generally of a fibro-cartilaginous structure. Constitutional and traumatic conditions give rise to hyperplasia. The tissues of joints may also be affected; therefore, under the direct influence of either of the above, fibrin may be deposited under the basement layer of the synovial membrane. In this nodule some few cartilage cells may be deposited, which, subdividing, form fibro-cartilaginous masses, and pressing inward cause the synovial membrane to protrude with it into the joint cavity. Increasing in thickness, it extends farther and farther until it hangs by a broad fold. By the constant influence of the movements of the joint, it rolls about and is stretched until the fold becomes elongated into a pedicle, which either remains intact or is crushed off. Thus originally growing outside of the joint proper, it is now a foreign body made up of fibro-cartilaginous structure and covered with synovial membrane. This same method of development causes osteophytes to becomes loose bodies within joints.

In the fifth class, injury to a joint may chip off a piece of cartilage or bone and cause it to fall into its cavity, or it may often set up an inflammation of the articular cartilage and underlying bone and cause it to exfoliate and drop loose. The pathological condition which results in this process is as follows: The loose body has been exfoliated, just as an injury to a tooth or bone may cause it to exfoliate without evidence of acute inflammation. Of all tissues, of none could it be more expected than articular cartilage that separation of pieces should take place without symptoms of active inflammatory process. Products of inflammation cannot be easily diffused through articular cartilage on account of its anatomical structure. It is a hyaline cartilage, made of cells arranged in symmetrical order, the interspaces filled in with hyaline matter having no blood-vessels, and its structure, therefore, not easily permeable. Traumatism may set up an inflammation at its base where it joins the bone. The nutriment is supposed to be supplied in hyaline cartilage through channels which connect the lacunæ in which are situated the cartilage cells (Klein's "Histology"). These channels and lacunæ make an intercommunicatory system, which is connected with the vessels in the perichondrium and underlying bone. Products of inflammation may also find their way into these channels and lacunæ, and occlude them, thus cutting off the nutriment supply. Now if traumatism sets up an inflammation at the base of the cartilage, where it is attached to the underlying bone, the superficial portion of the articular cartilage is shut off from its nutriment supply by the occlusion of the channels at its base. The free articulating surface of the cartilage has no perichondrium; the nutriment, consequently, is furnished only from the base and that portion of the perichondrium which surrounds the cartilage where it is attached to the bone. The increased products of inflammation cause the cells around the site of inflammation to necrose by pressure, and the superficial portion of the articular cartilage is pushed off or exfoliated, and drops as a loose body into the joint.

That such bodies are true chips of normal articular cartilage can be verified by microscopical examination and by the history of these special cases. In normal articular cartilage the cells near the surface appear flattened and parallel and more numerous; they gradually, as they near the base, become spherical, and assume a more vertical direction in columns. The case cited in the beginning of this paper, where a healthy individual, from violence to his joint, without any symptoms (save the acute synovitis) following, finds, after several weeks, a loose body of such dimensions, verifies to a great extent the theory of its origin by a quiet exfoliating process. It is out of the question to presume that the original injury chipped this piece off at the time of accident, for it would immediately have been detected. The patient, after having recovered from the acute synovitis, felt perfectly well for more than two months, following his occupation as a pedlar without ever noticing any abnormal condition of his joint except a slight swelling. He never detected the loose body until after two months, and surely its size is of such a nature that, had it been chipped off when he fell, it would easily have been detected by his physician, if not himself, for such a large body could not hide itself as smaller ones are wont to do. I have described this class a little more in detail for the reason that some writers [1] claim that pieces of articular cartilage and underlying bone are never exfoliated into a joint, but that these bodies which do resemble normal articular cartilage are only heterogeneous outgrowths from the synovial membrane.

In the sixth class the heterogeneous bodies form a separate class and can be accounted for in this manner. The synovial membrane has been proven in its normal condition often to contain cartilage cells in its structure (Kölliker, "Manual of Histology"). Under morbid conditions, such as a sprain or any irritation, activity is set up in these cartilage cells, which continuing to subdivide give rise to growths projecting into joints, which are finally snipped off by its movements and become loose bodies.

It is very important to study the pathology of this class of loose bodies, as the mode of formation and growth of such substances, lying within the knee-joint especially, has been the subject of much controversy. These frequently simulate the normal articular cartilages and underlying bone exfoliated or clipped off by accident so minutely that it has been a serious question in the minds of some eminent authorities whether normal articular cartilage is ever exfoliated, but that all such bodies found in the joints are but an outgrowth from the synovial membrane. There are distinguishing features enough between these two to overthrow this theory.

1. In these heterogeneous bodies the matrix of the cartilage is fibrous, and we have a fibro-cartilaginous body, while in the true cartilage the matrix is hyaline.

2. The arrangement of the cells in true cartilage is generally regular and different from the promiscuous deposition of the cells in the heterogeneous variety.

3. Autopsies in some cases have shown that the loose bodies accurately fitted the depression which existed at the lower end of the condyles of the femur.

The concave surface of the specimen is made up of depressions and elevations, as if exfoliated off a condyle, and again its convex surface exactly corresponds and resembles the lower end or articulating surface. Such a body does not resemble an outgrowth from the synovial membrane. If such an heterogeneous body would have been rolled about in a joint for some time and smoothed off by attrition it is not likely that one side would be depressed at the expense of the other. Its history, the pathological theory of its origin, its histological as well as gross appearance are conclusive proofs that this specimen is a piece of real articular cartilage, and is another illustration that such bodies are normal articular cartilage exfoliated without acute inflammatory symptoms.

[1] Professor Humphry: British Medical Journal, 1888, p. 710.

Symptoms.—When these loose bodies are very small they give rise to hardly any symptoms, and the patient may be unaware of their existence until one of them is caught between the articulating bones. However, a persistent, painless, or nearly painless effusion into a joint is always a suspicious feature of a foreign body in it. These certainly can only then be detected by palpation, if the joint is not too much distended. If a single one is only present, and of sufficiently large size, the patient may by chance feel a mobile little swelling in his joint, which, if he tries to grasp between his fingers, slips from them and is lost to touch, probably for some days, until it again attracts his attention by its movements. From the analogy to a frightened mouse which is driven into its hole these bodies have been called by the Germans "Gelenkmous," joint-mouse.

Oftener such a foreign body is detected in a much more unpleasant manner. While following his ordinary pursuit, or while walking, he is suddenly seized with a severe pain, and unless he supports himself (if body is in knee-joint) he falls. The muscles of the limb are in a state of contraction, the joint being therefore fixed, and the patient feels that a change in the position of the limb will relieve his pain. Sometimes he is able to do this himself, or he may have to get someone else to come to his assistance. The patient then obtains relief, with probably a slight effusion from irritation to the synovial membrane which may last for a few following days. All symptoms then disappear until the body is again caught between the bones.

If such attacks come repeatedly, and even though there is no palpable evidence, it is conclusive proof that a foreign body exists in the joint, which is caught between its articular surfaces and gives rise to these excruciating pains. A subluxation of a meniscus may also give rise to the same symptoms, and may therefore mislead us in our diagnosis. If the body is freely movable it is not likely to be the meniscus. When, after careful observation, one detects a movable body in connection with a joint, one must also be certain that it is inside of its cavity, for there are often, in some patients, outside of their joints, lipomatous nodules or anomalies of the fascia which have sometimes a certain amount of mobility and have been mistaken for intra-articular bodies. But these have limited range of motion, and are always found in the same place, and what is characteristic, never disappear, but, on the contrary, can always be detected in the same situation. They do not play "hide and seek." The character of the body can rarely be made out until removed; their size often seems larger than in reality.

Treatment.—The only positive cure of the symptoms and inconveniences these bodies cause is removal. Palliative measures are often adopted, such as fixing them in some harmless portion of the joint by some suitable apparatus, as bandages, splints, etc. But these are only temporary and unreliable. The operation for their complete removal is very simple and may be performed in two ways—the direct, that is, cutting down on to the body, opening directly the joint; and the indirect or subcutaneous method.

Years ago, before antiseptics played such an important *rôle* in the treatment of wounds, the direct method was superseded by the indirect on account of the frequent suppuration which followed wounds of synovial and serous cavities. To-day, because we have learned how to clean our hands, the patient's skin, how to keep our instruments aseptic, suppuration should not follow, and the direct method has again assumed the ascendency.

The indirect method can briefly be described. A long tenotome is introduced under the cleansed skin, and freely moved about, preparing a cavity in the periarticular tissues large enough for the reception of the body. Then, with the tenotome still subcutaneous, the synovial membrane is freely opened to admit of the body being squeezed into the newly made pouch; here it may remain for a few days until we think the rent in the synovial

membrane has closed, when it may then be cut down upon and removed from its new situation. This, one can perceive, is not a very neat surgical procedure. We do not know what damage we are doing, working as it were in the dark, and at the same time we are not always sure that we are able to squeeze the body out through the subcutaneous rent.

The direct method is very simple, and meets with far better results if strict antisepsis is followed. The skin is thoroughly cleansed with soap and water, shaved and washed with ether and bichloride solution. Iodoform ether is then poured over the area or field of operation. The assistant, whose hands and finger-nails have been thoroughly cleansed and disinfected, grasps the body between his fingers and holds it there while the surgeon cuts freely down upon it, through the skin, fascia, periarticular tissue, and synovial membrane, when, with a little pressure the body is quickly squeezed out of the joint. The tract should be immediately compressed by the assistant while the operator sutures the skin. Proper dressings are applied, the limb placed on a splint, and patient put to bed. If the body has a pedicle, it must be snipped off. If the assistant carelessly allows the body to slip from his grasp, we sometimes have to introduce a fine tenaculum forceps to extirpate it. This, of course, complicates the operation. If much manipulation has been necessary, a drainage-tube would be safer inserted into some dependent portion of the joint. The after-treatment simply consists in immobilization of the joint and watching for evidences of suppuration. Should such ensue, strict antisepsis has not been followed, and the concomitant symptoms and processes require a surgical interference, the details of which are foreign to the scope of this paper.

243 East Forty-ninth Street.

A CASE OF ACUTE ANÆMIA FROM POST-PARTUM HEMORRHAGE TREATED BY INTRA-VENOUS SALINE INJECTION.

By ALVAH M. NEWMAN, M.D.,

late house surgeon of charity hospital, new york.

Maria McK——, aged thirty-four, married, third pregnancy. This patient entered the waiting pavilion of the New York Maternity Hospital, service of Dr. H. C. Coe, on the evening of November 7th, in a decidedly cachectic condition, the result of malarial poisoning of long duration. She was of a nervous disposition, and complained of general lassitude. She was in the ninth month of her pregnancy, having passed through the preceding time without the slightest difficulty. At eleven o'clock on the evening of her admission labor began. The pains were rather weak, and so continued until 4 A.M. of the following day, when they approached the normal in acuteness. At 5 A.M. the patient entered the delivery-room, the os being one-quarter dilated, *i.e.*, admitting two fingers easily. Here she was antiseptically prepared, a bichloride bath 1 to 2,000 and vaginal douche 1 to 8,000 being given.

The urine was drawn by catheter, and the contents of the lower bowel were evacuated by enema. The second stage of labor was precipitate, expulsion being effected by three or four vigorous pains at about two minutes' interval. After the birth of the child blood for the first time was seen issuing from the ostium vaginæ. I immediately terminated the third stage, expressing the placenta by the Credé method. With the birth of the placenta came an immense gush of blood, making a marked impression upon the patient and her pulse. She now became very restless, the face pale, and the pulse at the wrist weak and rapid. A hypodermic injection of 30 minims fluid extract of ergot was given in the thigh, and this was quickly followed by 15 minims tincture digitalis administered in the same way. I now introduced my hand into the uterine cavity to remove remaining portions of placental tissue, should there be any, while at the same time massage of the fundus uteri was made with the other hand. Nothing was found in the uterus, but the general relaxation of the organ was immediately noted. At this time there was no distinction between vagina, cervix, and body of uterus, since only slight contraction had taken place after the birth of the child. As kneading had little or no effect, a large piece of ice was introduced into the cavity after first being dipped into hot water to soften all sharp edges. This again made but slight impression upon the hemorrhage from the relaxed uterus. A prolonged hot vaginal douche of one per cent. creolin was next given, while at the same time the abdomen was slapped forcibly with a wet towel, a measure recommended by the late Dr. I. E. Taylor. No effect being produced by this, it was immediately followed by hot intra uterine douches of the same solution, which lessened in a marked degree the severity of the hemorrhage, but had little effect in stimulating contraction of the uterus. Creolin was used here for both its antiseptic and its styptic effect. The patient's condition was fast becoming serious—her skin was cold and clammy, her respirations very superficial, and the pulse was hardly perceptible. Hot cloths were now applied to the precordia, and hypodermic injections of whiskey, tincture strophanthus, and tincture digitalis were administered. Hot bottles were placed about the patient, and the foot of the delivery-bed was elevated. I continued kneading the uterus, endeavoring to stimulate contractions, my assistants in the meanwhile bandaging the extremities. As the patient now showed marked symptoms of collapse, vigorous treatment was urgent. Sheet lint was soaked in vinegar, and with it I swabbed the uterine cavity repeatedly, while my junior assistant applied the faradic current to the abdomen. Our efforts were not in vain. The flabby uterus was regaining its tonicity, and the outgush of blood was reduced to a tiny stream—yet it still persisted. It was not the amount of hemorrhage that caused alarm, but the precarious state of the patient from the previous loss; every drop saved gave her an additional chance for the life which was now at its lowest ebb. I introduced Cusco's speculum into the vagina, and swabbed the uterine cavity with Monsell's solution of iron, doing this, however, with great circumspection, owing to the danger of sloughing, and the resultant focus for septic infection in the uterus.

As each of the preceding hæmostatics had failed to arrest entirely the hemorrhage, this application was made as a last resort, and it was successful—the flow being completely arrested at 7.20 A.M., one hour and ten minutes after the completion of the second stage.

I now gave my entire attention to the acute anæmia which existed, and the management of this seemed even a more difficult task than that of arresting the hemorrhage. An enema was given, containing one ounce of whiskey, four drachms of sodium chloride, and milk, making in all eight ounces, at a temperature of 100° F. This enema was repeated in half an hour. Stimulation was continued principally by the hypodermic use of whiskey and strophanthus, and the administration of black coffee at frequent intervals by the mouth. By these measures the heart so improved that the pulse could be appreciated at the wrist, yet lacking the positiveness of the normal pulsation. This was certainly a pulse of stimulation, as it would gradually fail as soon as the effects of hypodermic medication passed off. It became very evident that something more was needed than these measures to keep the patient alive, and establish a circulation necessary to carry on the physiological requirements of cell life.

I had endeavored to limit the circulation to the trunk by bandaging, and elevating the extremities, but even with this limitation there was a dearth of fluids in the vital organs. As the effects of the stimulation were progressively growing shorter in duration, and the patient's condition was not improving in the least, she being exceedingly restless, her lips blanched, and her facies almost cadaveric, I determined to resort to direct infusion.

The median cephalic vein of the left arm was exposed, and two ligatures were passed around the vessel, the lower of which was tightened. The cannula of the Collins transfusion apparatus was then inserted into the vein above, and, very slowly, ten ounces of Little's solution, temperature 100° F., were infused into the circulation.

The formula of the solution used was as follows.

R. Sodium phosphate	grs. iij.
Potassium chloride	grs. vj.
Sodium carbonate	grs. xl.
Sodium chloride	ʒ j.
Distilled water enough to make	ʒ xx.

The cannula being withdrawn, the vessel was ligated, and the wound dressed antiseptically. None of the unfavorable symptoms presented which sometimes occur after such an operation. Though still compressible, the volume of the pulse immediately increased, but shortly afterward diminished. It remained fair, considering the patient's previous condition, it being now 130 beats to the minute. It was still necessary to continue kneading the uterus, and owing to its tendency to relaxation, a second hypodermic of fluid ext. of ergot was given.

The infusion of salt solution not only made a marked impression upon the pulse, but the skin lost its clammy feel, and the mucous membranes in contiguity with the skin gave evidence of slight injection. The latter was all that I could expect, since the saline solution had simply added volume to the diminished amount of blood in circulation. As the patient rallied under this treatment she became restless, complained of great thirst, and was with difficulty kept in the inclined position, even after a hypodermic injection of 7 minims of Magendie's solution. A second dose in the afternoon gave her a refreshing sleep of twenty minutes.

At 4 P.M., owing to the great thirst experienced by the patient, a high enema of salt solution with half an ounce of whiskey, making eight ounces in all, was given at the suggestion of Dr. H. C. Coe, the visiting surgeon.

This enema was repeated in an hour, and very effectually relieved the symptoms, while at the same time it improved the pulse, which had diminished somewhat in volume as a result of loosening the bandages on the extremities.

At 5.30 P.M., the pulse was 106, and fairly strong. From this time until the following morning the patient was very comfortable, occasionally complaining of her inclined position, which was gradually changed during the night, to the horizontal.

At 7 A.M. the following morning the patient was transferred to the ward, feeling very well; pulse 84, temperature 100° F. About one hour later the pulse was 100, and so remained for five days, the temperature averaging about 101° F.

During the first three days after delivery vaginal douches of carbolic acid, two per cent., were given every four hours, and intra-uterine douches of bichloride 1 to 8,000 every twelve hours. These douches were lessened in frequency toward the end of the week, when they were discontinued, as there was not the slightest evidence of fetor, although each washed away friable clots, such as are always seen after the use of iron styptics.

The medical treatment during convalescence was limited to quinine sulphate, grs. v., and fluid ext. of ergot, ʒ ss., t.i.d. For the first three days her diet was entirely fluid, comprising milk, milk-punches, egg-noggs, and beef extract, administered at three-hour intervals in small quantities. Her convalescence was rather slow, but uninterrupted. When last seen, four months after delivery, she was in perfect health. It is not the rarity of post-partum hemorrhages, or the various methods employed in arresting the flow of blood in this case, that prompts its report, but the success attained in the treatment of the resulting acute anæmia by direct infusion of saline solution.

For exhaustive diseases and collapse due to acute anæmia, transfusion promised to the theorist a brilliant advancement. But, after many attempts during the past, transfusion of blood has been, I may say, entirely suspended, owing to the various difficulties attending such procedure. The care necessary in the details of this operation, when time is most valuable, and the difficulty of finding a suitable subject from whom to obtain blood, are matters which have discouraged many firm supporters. It is true that a few cases of success have been reported, and certainly success was a possibility if the emergency could be anticipated. But how many surgeons go prepared to meet these sudden and fatal cases? Many a life has been sacrificed, no doubt, owing to the disbelief in intra-venous injections. But since the introduction of this less formidable operation in the early part of this century, for the exhaustion of Asiatic cholera, it has risen slowly but steadily in esteem, and may be well called a life-saving measure.

Of the nineteen cases reported by Dr. W. T. Bull, some time since, in his paper on intra-venous injection, thirteen entirely recovered. It postponed the fatal issue in three, and had little or no effect upon the remaining. Since Dr. Bull's writing, several individual cases have been reported by others as successful.

The injection fluid used in these cases varies slightly, Schwarz's fluid being used in ten of the nineteen cases. This consists of water, ʒ xxxij.; chloride of sodium, ʒ jss.; carbonate of soda, grs. xv. The quantity infused depends entirely upon the severity of the case—eight to ten ounces is generally infused, and repeated if necessary. In my case, the high enemata of salt solution assisted very materially, thus avoiding the necessity of a second infusion.

In the employment of this measure one point is very essential—do not delay until your patient is moribund, and then infuse the solution, feeling assured that the patient is beyond all aid.

Your conclusion is well drawn: "It was an uncalled-for operation." You may get a slight stimulation, and that is all, for your trouble. The first three cases of infusion I saw while a student exemplified the above; it is needless to state the results. I am now fully convinced that two of the three cases might have been saved by an earlier endeavor. The hypodermic syringe holds such an important place in the minds of practitioners as an emergency ultimatum, that the pathological state which they are treating is entirely forgotten. Stimulating the fagging heart cannot avail when the circulating fluid is nearly exhausted. It is useless to pump harder at a dry well.

Inject the saline solution, using a foundation syringe in the emergency, and do it early. And here we meet an encouragement to this simple operation in the statement by Schwarz, and also by von Hacker, that the hydræmia arising from the injection of a salt solution, though greater than that from blood-transfusion, persists for a shorter time; and that the regeneration of the blood-corpuscles after transfusion of blood requires more than double the time required after saline injection. It is true that one of the principal functions of the blood is lacking in this fluid, *i.e.*, its power to convey oxygen to the tissue. But since the immediate danger is due to the disturbed relation between the calibre of the vessels and the quantity of blood contained in them, and not to the loss of red blood-cells, we have in the method of direct infusion the most rational means known at present for meeting the indications.

The Time when Children are Born.—Dr. A. A. Hamilton reports, in the *Indiana Medical Journal* for April, 1891, one hundred consecutive cases of childbirth in which the exact time of delivery was noted. From this he found that exactly fifty of the children, or one-half of the entire number, were born during the daytime, or between six o'clock in the morning and six o'clock in the evening.

PRACTICAL RESULTS OF THE OPERATION FOR LACERATED CERVIX UTERI.

By H. W. MITCHELL, M.D.,

NEW YORK.

The operation of trachelorrhaphy aims in its particular object to restore the contour of the cervix uteri to its normal condition. A higher and vastly more important aim of this operation is not only to restore the contour of the cervix, but to restore its future usefulness also. This is of the greatest importance. A patient who undergoes this surgical procedure should be so far restored to her original and normal condition as to enable her to assume future pregnancies, and to undergo the act of parturition safely and successfully, and without a repetition of the former lesion. In order that this may be accomplished, it is necessary that the operation be so conducted that when parturition does occur the parts shall undergo a natural degree of dilatation to allow the safe passage of the child without incurring a second laceration of the cervical tissues. The frequency of lacerations of the cervix uteri are familiar to every physician and gynecologist. Indeed, so frequent is this accident that many gynecologists have said that the parturition act is impossible without some degree of laceration following, and if one may judge from the number of cases that come under his professional observation, even in a limited practice, this opinion may seem to be well founded. The avoidance of this accident is not always possible, even in the hands of the most skilful physician, and even when he exerts his utmost care to prevent its occurrence. This is especially true of primiparæ, for in them the cervix uteri being of a small and virginal character, cannot always dilate sufficiently to allow the passage of the child's head without producing some degree of laceration. This is more than ever true where the patient is of a strong and vigorous habit, and where the expulsive labor pains are powerful and occur at short intervals.

Subsequent confinements of multiparæ are less liable to be followed by such lacerations, yet even in these the accident is not unfamiliar to most of us, and every physician can call to mind cases where primiparæ have undergone parturition safely and successfully, and multiparæ have become the victims of this accident.

As is well known the degrees of laceration of the cervix uteri vary in severity and extent; perhaps the greater number are of the unilateral variety, the laceration involving only the tissue of one side of the os tincæ. In others the laceration is of the bilateral variety, involving the tissues of both sides of the os. In this form of laceration the severity and extent vary considerably. In some the laceration involves only the tissues extending up to the inner os, in others the whole cervix is laid open, and consequently the parts become tumefied and everted, and gape like a horse's mouth. Still another variety of greater severity is the stellate form, where the laceration extends in several directions, radiating from the os outward and involving the larger part of the cervical tissue.

All these forms, namely, the unilateral, the bilateral, and the stellate, have their especial train of painful and distressing symptoms. While it may be true, and undoubtedly is true, that many cases of the simpler forms of laceration heal spontaneously, either partially or almost wholly, although I believe never wholly so, and require no surgical interference, such cases pass through life without any marked symptom, except perhaps a slight pain caused by the presence of cicatrical tissue. Such patients undergo subsequent confinements with comparative safety and ease. This may be due partly to the natural reparatory process of the tissue, and partly through individual insensibility to such a condition of things. It is a well-known fact that uterine tissue varies in sensibility in different individuals—some suffering a train of distressing symptoms, while others, with an equal extent of lesion, suffer little or no pain. In the bilateral and stellate forms of laceration this immunity from suffering rarely or never exists. Sooner or later the patient is made sensible that she is the victim of some ailment—perhaps not always conscious of what the ailment may be, but still knowing that she is not well—and that her health suffers from some cause which she does not always understand. A careful examination usually reveals the fact, and the laceration is answerable for her physical condition of suffering. The symptoms that follow an accident of this kind are well known to every one, and may be briefly summarized as follows: 1. Pain in the back and loins. 2. The sense of bearing down, more or less severe. 3. Leucorrhœa, more or less profuse. 4. Neuralgic pains of the cervix uteri. 5. Frequent sterility, pregnancy under such circumstances being often impossible. 6. Discomfort in locomotion and in sitting down. This is sometimes quite severe.

It is not infrequently the case that all six of these symptoms are present in a single case. The most common symptoms that have presented themselves to my notice are the first three above mentioned, namely, pains in the back and loins, the sense of bearing down, and leucorrhœa. This last symptom is the most frequent of all and is rarely absent.

I doubt if a woman can have a stellate or bilateral laceration, or even a unilateral laceration, of any marked degree or severity without suffering from leucorrhœa. Intercourse in such cases is frequently painful, and contact with this sensitive part must necessarily be distressing. Vaginismus is also a symptom, and when this distressing condition occurs, coitus becomes doubly painful. Sometimes sterility is the only symptom that attracts the attention of either patient or surgeon. Cases are by no means uncommon where a woman has given birth to a first child, and years have gone by without a recurrence of pregnancy. The surgeon is appealed to for a reason for this condition of things. He learns that the patient suffers little or no pain, and they have so little leucorrhœa as to lead them to think they have no uterine trouble. This form of sterility is very important to the mind of the surgeon, and an examination reveals a lacerated cervix, with all the conditions accompanying it which make other pregnancies impossible.

Cases also occur, and are by no means rare, where women abort at the third, fourth, or fifth month, without being able to assign any reason therefor. In such cases pregnancy duly follows successful intercourse, and the woman is happy in the belief that she is again to become a mother, when, without reason, so far as she knows, her labor is lost, and she suffers a miscarriage.

In the severer forms of laceration, those of the bilateral and stellate variety, all these symptoms are present, and in such cases the woman is not long in doubt of the fact that she is suffering from some kind of uterine trouble. In these modern days she can arrive generally at a clear understanding of her condition through the information imparted to her by her suffering sisters or gossiping neighbors. Few among them have not suffered themselves, or have some friend who has so suffered, so that when they apply to the surgeon for relief they have an idea, more or less definite, that the trouble is of a uterine character. When this accident occurs it is difficult, if not impossible, to detect it at the time of its occurrence. The hemorrhage that follows is usually regarded as a natural hemorrhage accompanying normal labor, and if it continues for a time after the lochia have ceased, it is still looked upon as natural uterine hemorrhage. A digital examination fails to reveal the true condition of things, for the reason that the soft and patulous state of the parts make it impossible to arrive at a diagnosis. Hence it is months or years afterward, when the patient's attention is directed to her distressing symptoms, that the physician learns the true condition of things. A laceration of the cervix uteri, if of a simple unilateral character, seldom requires surgical interference, and such cases as these usually do well when left to themselves, or at most re-

quire but slight local treatment to allay the inflammatory condition of the parts. Many such cases come under the practitioner's notice, and local applications of an astringent character, continued for a time, accompanied by a warm vaginal douche, either of plain water, or water to which some astringent is added, usually accomplishes all that is necessary.

In severer cases of unilateral lacerations, and in all, or nearly all, of bilateral lacerations, and I believe in every case of stellate lacerations, surgical interference is necessary, and in most of such cases it is imperative. The method of operating upon such cases as these becomes extremely important, and it is here that the point of this paper is made, namely, to restore the contour of the cervix uteri to its normal condition, and to restore also its future usefulness. Upon this point rests the entire importance of the procedure. How best this operation should be done is a matter that perhaps can be explained by a simple method, that has in the past yielded the best results, although its detail is varied somewhat by different surgeons. Yet in the vast majority of cases the method of operating is practically the same by all.

The patient presenting herself for operation should be prepared in the following manner: Her bowels having been emptied by a mild laxative the previous day, and her stomach kept empty of food, should be profoundly etherized. When under the full influence of the anæsthetic she should be placed in Sims's position, namely, upon the left side with her hips drawn down to the edge of the table. The operator, seated conveniently near her, should now introduce a speculum for the purpose of bringing the cervix into full view. To do this well, I know of no instrument better adapted for the purpose than the one I had the honor to devise, and which I take pleasure in presenting here. The expanded wings upon the blade of this instrument hold the upper labium out of the operator's way, and depress the lower labium, which are so apt to fall together, and thus impede the view of the operating surgeon. Having brought the cervix into view, either by the use of my own speculum or by any other, the operator seizes the part with a long uterine tenaculum. If the laceration be of the stellate or bilateral variety, the torn, swollen, and uneven condition of the parts totally obliterates the former os, and he must construct for himself a new os, somewhere among the irregular and shapeless parts that present themselves. It is my custom to introduce up to the fundus a long uterine sound, and having found the most direct route to the fundus, to construct the new os at that point, it being the most eligible one in the case. With a curved scissors, or a uterine knife, or both, the torn, shapeless, swollen, and everted parts are now cut away radically, until sound uterine tissue is reached. The cut edges are from time to time approximated by the aid of a pair of tenacula, and in this way the operator can see when he has removed sufficient tissue. When he has done so, he may close the wound by the interrupted silver-wire suture. Hemorrhage is controlled by the use of sponges on proper handles, frequently cleansed with hot water, to which is added a weak solution of carbolic acid or hydrarg. bichloride.

The method of using the suture in my hands is as follows: The silver wire, preferably No. 28, is threaded directly into the eye of a suitable uterine needle. The first suture is placed nearest the site of the new os. It is inserted deeply into the tissue on one side, and brought out at a corresponding point at the other. About four or five to the inch are usually necessary, although more may in some cases be needed. The wires are now twisted with moderate firmness, which approximate the cut edges of the parts perfectly. The twisted ends of the wire may be cut off, leaving them about one-half an inch in length. The cervix and the whole vagina may now be freely washed with water that has been boiled and cooled down to blood heat, with or without bichloride or carbolic. The speculum may now be removed and the patient put to bed. I do not allow the patient to be disturbed by an alvine dejection for the first five or six days. Micturition is usually accomplished without difficulty, and at the will of the patient. The diet is nourishing but light, and the patient kept perfectly quiet for the first week. Opiates may be used when necessary, but pain after such an operation is rarely present. At the end of the first week the patient may be allowed to sit up, and on the tenth or twelfth day after the operation the wires may be removed.

When the operation is done carefully in this way, and attention to details scrupulously observed, both in the care and cleanliness of the operation, and the subsequent care of the patient, healing by primary union is the almost invariable result. In a record of 200 cases of this operation, but 2 healed by granulation, the others healed by primary union. Of these 200 cases of lacerations of the cervix uteri, I have been able to follow 21 cases where subsequent confinements have taken place, and of these 21 cases, 8 have had more than one subsequent confinement. These 21 cases have been attended personally by myself, and I have had an opportunity of watching them for a considerable period of time. The result of these cases are given in a brief *résumé*, as follows:

Case I.—Mrs. A. S——, aged thirty-five, mother of one child, born three years previous to the operation. No pregnancies since. She suffered a severe bilateral laceration of the cervix, with all the accompanying symptoms of pain in the back, bearing down, and profuse leucorrhœa. She was operated upon May 2, 1884, in the usual way, the wound healing by first intention, which took place on the twelfth day. One year after she gave birth to a child at full term, without relaceration.

Case II.—Mrs. M. R——, aged thirty-five, mother of three children; the last was born eighteen months previous to the operation. She suffered from a severe bilateral laceration, with all the distressing symptoms which accompany this accident. She was operated upon May 9, 1884, and on the twelfth day her cervix had healed perfectly by primary union. She became pregnant immediately after, and gave birth to a healthy child at full term. No relaceration occurred, and she made a complete recovery.

Case III.—Mrs. N. S——, aged twenty-seven, mother of two children, the last born five years previous to the operation. Her laceration was very severe, and of the bilateral character. She also had a laceration of the perinæum, and had also four large external hemorrhoids. On May 20, 1884, the usual operation was done upon the cervix, and at the same time an operation was done upon the lacerated perinæum—the hemorrhoids were also removed by ligation and were cut completely away with the scissors. She recovered completely from all three operations, the wounds healing by primary union, except the hemorrhoidal wounds, which slowly granulated. One year later she gave birth to a child at full term, without relaceration of either the cervix or perinæum.

Case IV.—Mrs. M. G——, aged thirty-one, mother of one child, born two years and a half before operation. She suffered a severe bilateral laceration, the wound extending to the vaginal junction. She suffered severely from this difficulty, having lumbar pains almost continually, with profuse leucorrhœa, and her condition at the time of the operation was decidedly anæmic. On July 7, 1884, she was operated upon in the usual way, and on the tenth day the wound had healed perfectly. Fifteen months after she gave birth to a child at full term, without any relaceration of the cervix.

Case V.—Mrs. M. G——, aged thirty-five, mother of four children, the last born three years before the operation. She had a severe stellate laceration of the cervix, and had suffered almost continuous pain since her last confinement. She was quite anæmic, and her general health had suffered severely in consequence of her uterien lesion. On July 11, 1884, she was operated upon in the usual way, and on the twelfth day the wires were removed, the wound having healed perfectly by primary

union. One year after she gave birth to a child at full term, without relaceration, and in two years gave birth to a second child at full term, without relaceration. The last time I saw her she was perfectly well, and the cervix showed no signs of any trouble whatever.

Case VI.—Mrs. L. D——, aged twenty-five, mother of four children, the last born one year previous to the operation. She had contracted syphilis from her husband, and had at the time a decided syphilitic taint of a tertiary character. She suffered severely from syphilitic nodes upon the tibiæ, and had several rupial lesions upon her shoulders, and also post-cervical adenitis, and periostitis of the frontal bone, with severe headaches. She had a stellate laceration of the cervix, and suffered severely from lumbar pains, a sense of bearing down, with profuse leucorrhœa. I placed her upon specific treatment, and the operation was done on July 27, 1884. In spite of her bad condition the cervical wound healed kindly, and on the twelfth day she was well. She became pregnant immediately after, and in eleven months gave birth to a child, who showed no signs of syphilitic taint. The reason of this was, I believe, because she took specific medicine during her entire period of gestation. Two years after this child was born, she gave birth to a second, and the last time I saw her she was perfectly well, and had no signs of a relaceration of the cervix. Her syphilitic manifestations disappeared entirely.

Case VII.—Mrs. J. H——, aged twenty eight, mother of one child, born three years prior to the operation. Her laceration was of the bilateral character, very severe, and was accompanied by lumbar pains, bearing down, and leucorrhœa. Her condition was very anæmic and she presented a miserable appearance. On August 13, 1884, the usual operation was done, and the cervix healed on the thirteenth day without difficulty. Proper nourishment and care improved her condition materially, and fifteen months after she gave birth to a child at full term, without relaceration.

Case VIII.—Mrs. E. S——, aged thirty-eight, mother of six children, the last born two years prior to the operation. She suffered a severe stellate laceration of the cervix, the date of which could not be actually learned. The entire cervix was thickened and granular, and bathed with a copious and foul leucorrhœa. After a course of preparatory treatment, lasting about two weeks, and consisting of copious astringent vaginal douches and applications of tincture of iodine every second day, she was rendered fit for an operation, which was done on November 14, 1884. On the twelfth day the wound had healed by primary union, and she was discharged. Thirteen months later she gave birth to a child at full term, and two years after this confinement she gave birth to a second child, without any relaceration of the cervix whatever.

Case IX.—Mrs. M. C. M——, aged twenty nine, mother of three children, the last born eighteen months previous to the operation. She suffered a severe bilateral laceration of the cervix, and when I saw her she was suffering from lumbar pains, severe bearing down, and a profuse leucorrhœa. The torn edges of the cervix were thickened, granular, and everted, and intensely painful. A course of preparatory treatment similar to that of Case VIII. was continued for two weeks, and on November 27, 1884, the operation was performed. The wound healed by first intention and her symptoms at once ceased. Fifteen months later she gave birth to a child at full term, and in fifteen months again gave birth to a second child at full term, and the last time I saw her she had no relaceration whatever.

Case X.—Mrs. S. H——, aged twenty-nine, mother of three children, the last born one year previous to the operation. Her laceration was of the bilateral variety and very severe, with all the distressing symptoms accompanying it. On December 7, 1884, an operation was done in the usual way, from which she recovered duly. Two years after she gave birth to a child at full term, and without relaceration of the cervical tissues.

Case XI.—Mrs. M. S——, aged twenty four, mother of two children, the last born fifteen months prior to the operation. She suffered a severe stellate laceration of the cervix, and a laceration of the perinæum, which extended completely through the sphincter ani. She had a slight rectocele which was aggravated by habitual constipation. On January 21, 1885, an operation was done upon the cervix, and upon the perinæum. Although both operations were quite extensive, she recovered completely, the wounds healing kindly by primary union. Twenty months after she gave birth to a child at full term, without relaceration of either the cervix or perinæum, and a year after she gave birth to a second child of large size, and owing to the fact that she persisted in walking around the room during the first and part of the second stages of labor she suffered a relaceration of both cervix and perinæum. After her confinement both relacerations were found to be of so slight a character that a second operation was not deemed necessary, and the last time I saw her she was enjoying good health, and with no inconvenience from her second laceration.

Case XII.—Mrs. J. W——, aged thirty-three, mother of three children, the last born three years prior to the operation. At the birth of this last child she suffered a severe bilateral laceration of the cervix and a laceration of the perinæum. She had three pregnancies which ended in abortions at about the fifth month in each case. When I saw her she was anæmic, suffered from lumbar pains, profuse leucorrhœa, and ovarian neuralgia. An operation was done upon the cervix and perinæum January 30, 1885. Both wounds healed kindly in the usual time by primary union, and she was placed upon a generous diet, which produced a marked change for the better in her general condition. Thirteen months later she gave birth to a child at full term, without a relaceration of her cervical tissues.

Case XIII.—Mrs. C. H——, aged thirty-three, mother of three children, the last born eight months prior to the operation. She suffered a severe bilateral laceration of the cervix and a laceration of the perinæum. She suffered the usual symptoms of lumbar pains, of bearing down, and leucorrhœa. On May 11, 1885, an operation was done in the usual way upon both cervix and perinæum. The wounds healed kindly by first intention. One year later she gave birth to a child at full term, without relaceration.

Case XIV.—Mrs. M. L. G——, aged thirty-five, mother of three children, the last born two years prior to the operation. She suffered from a severe stellate laceration of the cervix, and also a laceration of the perinæum. Three pregnancies were followed by abortions at about the fourth month, as a result of her lacerated cervix. The parts were swollen, granular, and everted, and intensely painful, and beside this she had a cystocele and a rectocele. On May 13, 1885, an operation was done upon her cervix in the usual way, and also upon the perinæum, which cured her cystocele and rectocele both. The cervical and perinæal wounds healed kindly by primary union, and on the twelfth day she was well. Eleven months later she gave birth to a child at full term, and nineteen months afterward gave birth to a second child at full term, without relaceration of her cervical or perinæal tissues.

Case XV.—Mrs. S. L——, aged twenty-nine, mother of four children, the last born fifteen months prior to the operation. She had a severe stellate laceration of the cervix, with all the accompanying distressing symptoms. On September 6, 1885, an operation was done upon her cervix, which healed by primary union on the tenth day. Fourteen months after she gave birth to a child at full term, without relaceration of her cervix.

Case XVI.—Mrs. J. K——, aged twenty-four, mother of one child, born one year prior to the operation. Suffered a bilateral laceration of the cervix of a severe nature. On November 23, 1885, an operation was done in the usual manner, and healing by primary union duly fol-

lowed. Thirteen months later she gave birth to a child at full term, without relaceration.

Case XVII.—Mrs. E. B. B——, aged twenty-eight, mother of one child, born two years prior to the operation. Suffered a severe bilateral laceration of the cervix and a laceration of the perinæum. Her condition was decidedly anæmic, and she suffered the usual train of distressing symptoms. On December 27, 1885, an operation was done upon both cervix and perinæum with a good result. Eleven months after she gave birth to a child at full term, and sixteen months after gave birth to a second child. She suffered a slight relaceration of the cervix, but not of the perinæum. No operation was necessary, and the last time I saw her she was quite well.

Case XVIII.—Mrs. A. W——, aged thirty-two, mother of a child born eleven years prior to the operation, had a second child eight years prior to the operation, and five months prior to the operation gave birth to twins at full term. Suffered a severe stellate laceration of the cervix, which was torn into almost a shapeless mass. Her symptoms were very severe. On February 7, 1886, an operation was done and the parts were restored to an excellent condition. One year later she gave birth to a child at full term, without relaceration, and a year later she died of phthisis.

Case XIX.—Mrs. C. M——, aged thirty-two, mother of one child, born two years prior to the operation, and six months prior aborted at the fifth month. She suffered from a severe bilateral laceration of the cervix. An operation was done on May 14, 1886, with a good result. Two years later she gave birth to a child at full term, without relaceration.

Case XX.—Mrs. E. M——, aged twenty six, mother of one child, born one year prior to the operation. She suffered a stellate laceration of the cervix and a laceration of the perinæum, which extended through the sphincter ani. She had also a slight vesicocele and a rectocele. Her symptoms were specially distressing. She was operated upon July 3, 1886, and both cervix and perinæum closed to their natural condition. She recovered duly, and fifteen months later gave birth to a child at full term. Eighteen months after she gave birth to a second child at full term, without relaceration of either cervix or perinæum. Both the rectocele and vesicocele were radically cured by the operation.

Case XXI.—Mrs. M. R. S——, aged thirty, mother of two children, last born six years prior to the operation. Within a year following this last birth she aborted twice between the fourth and fifth month in each case. For five years prior to this operation she had not been pregnant. She suffered a severe stellate laceration of the cervix, with the usual train of painful symptoms. On November 10, 1887, an operation was done with a good result. In January, 1891, she gave birth to a child at full term, without relaceration of her cervix.

By a reference to the foregoing 21 cases it will be seen that they were all of a severe form of laceration. In 7 cases there was a laceration of the perinæum; in the other 14 cases the cervix alone was torn. In one of these cases, where both cervix and perinæum were lacerated, the case was still further complicated by hemorrhoids.

In reference to the character of the lacerations, it will be seen that 12 were bilateral lacerations and 9 were of the stellate variety. In all of the cases where both cervix and perinæum were torn, a double operation was done, and in the case complicated with hemorrhoids, three operations were done at the same sitting. These cases were not selected, but were taken as they occurred and the result reported.

In 13 of these cases the patient had one child subsequent to the operation, and in eight cases the patient had two children subsequent to the operation. Relaceration of the cervix occurred but in one case, and, as above stated, this was so slight as not to make a second operation necessary. If the above cases can be taken as a criterion by which to judge of the practical results of this operation upon the cervix, then it has succeeded in doing what is chiefly desired, namely, to restore the future usefulness of the organ. Without this practical result the operation would be futile and of no value. If we may judge by 21 cases, and this is all I have had a personal opportunity to observe where I was familiar with all the details, then we may say that the operation is a proper and successful one, and accomplishes the following practical results: 1. To diminish pain and irritation following upon such a distressing lesion. 2. To relieve the sense of bearing-down. 3. To cure the exhausting discharge caused by the leucorrhœa and to restore the parts to their natural and healthful condition, and paramount to all other considerations, to restore its natural functions that future pregnancies may take place in a natural and healthy manner, and without subjecting the patient again to the same train of distressing and painful symptoms that led her to seek relief by a primary operation.

Clinical Department.

AN ACUTE CASE OF PROGRESSIVE MUSCULAR ATROPHY.

By ARTHUR C. BRUSH, M.D.,

BROOKLYN, N. Y.

The following interesting case, which I have ventured to call an acute form of progressive muscular atrophy, is, I think, an anomalous one. The patient presented himself at the Brooklyn City Dispensary on March 26th, with the following history: He was twenty-eight years of age, married, born in Ireland, and a blacksmith by occupation. He had always been a healthy man, and never touched liquor or had any venereal disease. His family history was good. On March 17th, only nine days before, he became intoxicated and slept exposed to the severe cold of that night. Since then he has not been able to work, having rapidly lost strength, and he has noticed that his muscles have become much smaller. He has a few sharp lightning pains in his limbs, but at no time have there been any other disturbances of sensation.

Examination shows all the muscles of the trunk and limbs to be atrophied, the condition being most marked in the extensors of the arm and leg; and the patient thinks it commenced in them. The skin hangs in folds, and fine fibrillary contractions can be felt in the affected muscles. He walks by shoving the feet, which are sometimes turned in, sometimes turned out. There is no muscular paralysis; the reflexes are feeble, and sensation is normal. Both electrical currents produce muscular contractions. The intelligence seems good, except that he cannot pronounce or spell the name of the street where he lives; and his articulation is very imperfect. The pupils are normal, and there are no disturbances of sight or hearing. There are no bladder, rectal, or sexual troubles.

By April 6th his muscular atrophy had become much more marked, and his breathing diaphragmatic from involvement of the intercostals; the pulse was rapid and irregular. The night before he fell, striking the back of his head, which, however, showed no lesion; but in the morning he awoke with complete paralysis of the lips, tongue, larynx, and pharynx. The reflex and electrical contractions were then very feeble. He remained in this condition until April 19th, when he developed a pneumonia of which he died. Unfortunately no autopsy could be obtained.

The diagnosis of this case is of course very obscure. It was not simple congestion of the cord, nor myelitis, nor myelitis of the anterior horns; for there were no disturbance of sensation, no bladder or rectal troubles, and the loss of muscular power was due to atrophy and not to paralysis.

There are but two diseases of the cord characterized

by fibrillary contractions and progressive muscular atrophy, and these are both chronic; and in lateral sclerosis there are also disturbances of sensation, and the atrophy is followed by permanent contractions.

The history resembles that of progressive muscular atrophy running an acute instead of a chronic course. The points of interest are the absence of family history, which is usually marked; the rapid involvement and atrophy of the entire muscular system of the body; the distinct history of a cause; and the sudden development of bulbar paralysis; but this latter also occurred in two reported cases of progressive muscular atrophy.

INTERSTITIAL PLACENTITIS.

By JOHN J. MORRISSEY, M.D.,
HARTFORD, CONN.

On Friday, January 2, 1890, I was summoned, about 7.30 P.M., to see Mrs. B——. On arriving at the house I found a large, fleshy woman weighing probably in the neighborhood of one hundred and eighty pounds, reclining on the bed with pallid (I use the word advisedly) features, and who on my entrauce begged me to do something for her. There was another woman in the room who, on my inquiring, told me that Mrs. B—— had been in labor since 3 A.M., a period of some sixteen hours. The pains had been of an intermitting character, accompanied with little expulsive force, and not sufficiently acute to compel her to remain in bed, until about an hour before my arrival, when they suddenly became more intense for half an hour, and then entirely ceased. The patient herself supplemented this information by saying that she was the mother of eleven children, and had never found it necessary to require the services of a physician, as she had in all her previous confinements never been over two or three hours sick, and had always got along with such assistance as the midwife rendered. I know that her health had been generally excellent, as I had in the past five years frequently prescribed for her husband and children, but never for herself. I found her pulse to be 120, feeble, and now and then intermitting. On examination per vaginam, I felt the vertex presenting L.O.A., and as there appeared to be absolutely no contracting power exercised by the uterus, I applied the short forceps, and with very little exertion, scarcely any in fact, I extracted a macerated fœtus of, I should judge, about eight and one-half months. It was perfect in shape, except that the head was considerably elongated, the cranial bones overlapped each other, and the feet had every appearance of talipes varus.

On placing my hand over the fundus of the uterus, notwithstanding the fact that the fœtus had been expelled, I found the uterus still remained uncontracted. I made some traction on the cord, and finding, despite my efforts, that the placenta still remained firmly adherent, desisted, administered a drachm of ergot, and waited. The pulse in the meantime had not fallen, but persisted in the same rapidity as before delivery, the woman was perfectly conscious, and gave vent to an ejaculation of gratitude when the fœtus was expelled. After waiting some fifteen to twenty minutes, and still finding the placenta firmly fixed, I determined to follow up the cord and deliver if necessary by manual force. Under the circumstances, with no assistance only such as could be given by an unintelligent midwife, with a woman who had undergone the pangs of an exhausting labor, and was then completely worn out, with a rapid and feeble pulse, and features that indicated something yet to be discovered back of all these signs, I did not think it safe to use chloroform. After antiseptic precautions I followed, without much difficulty, the cord up to its juncture with the placenta and strove to peel the latter off. I found it to be so firmly adherent that it seemed to me to be intimately connected with the muscular tissue of the uterus itself. I finally got down a portion of it and snipped it off. It was a piece of the placenta about as large as the palm of the hand, through the centre of which the cord was running, while from each side there were some six or seven fatty prolongations about the size of the little finger. I now sent for Dr. Ingalls, who quickly responded. In the meantime I had given whiskey with more ergot, but the patient appeared unresponsive to the effects of the stimulant.

Dr. Ingalls introduced his hand, but after considerable exertion failed to bring away any more of the placenta, and owing to the extreme prostration of the woman we finally desisted from further attempts.

I saw her again the following morning, but instead of being in bed she was partly reclining on some chairs, as in this position she stated "it was easier for her to breathe," yet there did not seem to be any great amount of difficulty to her respiration. Her pulse had fallen to 115, and she appeared to be quite comfortable. There had been no hemorrhage whatever, not even the ordinary amount consequent upon labor. On the evening of the day upon which I made my second visit she gradually grew weaker, but her relatives did not consider her condition to be at all alarming until about six the following morning, when she rapidly went into collapse and died an hour afterward. To my great regret there was no autopsy.

It seems to me to be difficult to determine exactly the cause of death, from the meagre information derived from the deceased's former history. Was it an embolus depending upon some antecedent disease, as Bright's or syphilis? As to the latter, there was no enlargement of the glands or other evidence of syphilitic infection, and there were some six or seven children living, the youngest being three years of age, with no sign of specific taint. It was D'Outrepont, who, about 1830, drew attention to the fact of the influences of diseases of the placenta upon the nourishment and life of the fœtus, and Ercolani, who described, under the name of "cellular hyperplasia and hypertrophy of the parenchyma of the placenta villi," a disease that is characterized by the extensive multiplication of the cellular elements in the villi to such an extent as to obliterate the blood-vessels, and give the placenta a hard, dense appearance and feel. This has been called by other writers sclerosis of the placenta, and has been attributed to over-production of fibrous tissue. Barnes has described a simple fatty change without other pathological processes, but now it is generally believed to be subsequent to other degenerative changes, most frequently an abnormal development of fibrous tissue—interstitial placentitis. As there are no capillaries in the maternal portion, many observers have denied that an inflammation of the placenta can take place, but certainly pathological changes are found in the placenta analogous to those seen in cirrhosis of the liver. The diagnosis of interstitial placentitis was confirmed in the present case by a microscopical examination at the hands of Dr. Wolfe, of this city.

FOREIGN BODY IN THE LARYNX.

Dr. Lachlan Tyler, of Elkhorn, W. Va., reports a case of death from impaction of a piece of meat in the larynx, upon which he performed an autopsy while serving as coroner's physician in Washington, D. C. The subject was a Frenchman, about sixty-five years of age, an inmate of the workhouse in Washington. One day, after eating a hearty dinner, he arose from the table and had taken a step or two toward the door of the dining-room, when he was seen to fall to the floor and almost immediately died. At the autopsy the brain, heart, lungs, and all the abdominal viscera were examined without any condition being found to account for the sudden death that had taken place. Finally, on opening the larynx, a piece of gristly corned beef, one inch long and half an inch in thickness, was found firmly impacted in the glottis. It was so tightly wedged in that it required considerable manipulation and some force to dislodge it.

NORMAL ALBUMINURIA.

FEW, if any, insurance companies will accept a risk, if albumin has been demonstrated to exist in the applicant's urine, and while the examining surgeon may personally be convinced of the trifling nature of the cause which has produced the trace discovered, the company considers it inexpedient to discriminate, and hence places all such cases in the same class as undesirable.

Undoubtedly albumin can be found in many instances where nephritis does not exist and where it does not subsequently develop, and much injury and injustice is done to those who are unfortunate in one sense and fortunate in another, as the victims of temporary, cyclic, regularly or irregularly intermittent, or any other form of benign albuminuria. These individuals are the victims of a science which goes far enough to discern the signal, but is not in every instance able to make out whether it is really a signal of danger. So important is this question of the forms of albuminuria which are not of necessity dangerous to life, that everything bearing upon it should receive careful consideration.

Senator ascertained to his own satisfaction that there was a "physiological albuminuria" some nine years ago, and believed that the source of the albumin is the epithelia of the urinary passages, and of the tubules of the kidney which undergo periodical desquamation.

The difficulty of demonstrating the slight amount of albumin present in health lies in the fact of its high state of dilution. Posner has proposed a method of detecting the presence of small quantities of albumin, which is a modification of the process advanced by him in 1886, and which consisted in the free addition of acetic acid to the urine, which converted the albumin into a non-coagulable acid-albumin. After evaporation and filtration the albumin is made apparent by the ferro-cyanide of potassium.

This he has modified as follows: Precipitate with alcohol, wash the precipitate with hot alcohol, then with cold ether, and throw upon the filter boiling concentrated hydrochloric acid. If albumin is present on the filter a beautiful violet color is obtained.

Pavy has given an excellent description of the transitory albuminuria tending to recur in a cyclical manner, and many have since added their observations on this interesting phenomenon.

It is now quite generally accepted that the condition may arise from dietetic causes as well as from muscular exercise, and some observers, among them Falkenheim, have found it in certain individuals always following rest in bed. In one case lying upon the left side produced a marked increase in the albu nin, due it was thought, to compression of the renal veins by a large spleen.

Dr. Lewis, of Hartford, has found that although from six to ten per cent. of persons who apply for life insurance have more or less albumin in their urine, still the mortality rate "both of selected lives and the general public" rarely exceeds three per cent., from which he infers that only about thirty to forty per cent. of albuminuria cases terminate fatally. While it is well to bear in mind the possibility of albuminuria without nephritis, we must not fall into a habit of regarding the presence of albumin as trivial and thus overlook the really serious cases.

OUR NATIONAL HOLIDAY AND ITS MINOR SURGERY.

SOME five years ago we published an article of length on the subject of the "Toy Pistol Wounds" which the youth of our country annually take pleasure in self-inflicting, and each succeeding year we have felt it wise to refresh the minds of our readers with a brief note on the importance of the subject. These wounds are small, but they possess dangers far out of proportion to their size. They generally involve the hand, and are punctured wounds inflicted by the entrance of bits of metal caps, wadding, and powder. The reports in the lay press, during the month of July, attest the frequency of lockjaw and other septic complications.

The little wounds should receive early and careful attention. Under cocaine a free incision may be made to the bottom of the wound, and all foreign bodies carefully removed. Thorough disinfection with a sublimate solution of suitable strength and loose packing with antiseptic gauze follow, the dressing to be changed frequently.

DO LOBSTERS CONTAIN ARSENIC?

TO-DAY, when Boston is mentioned in New York society, it is no longer the bean question which rises with irresistible force to the imagination. At least, if beans are thought of at all, it is only in a secondary and supplementary way. What has effected this vast change is the unprecedented susceptibility of the Boston constitution to minute doses of arsenic, an idiosyncrasy which has already made the name of Boston heard, and, indeed, familiar, in distant lands where the bean never had the power to penetrate.

No other event since the days when they turned their Back Bay into a teapot, and the men left their wives at home while they went to the stag tea-party and did their own "pouring," has anything so completely taken possession of all classes of society as has arsenic. To add to the excitement, a whole jury—twelve men, good and true—were recently poisoned by eating canned lobster. While no doubt exists that the poisoning was due to arsenic, the questions which have to be determined are: 1. Has the Bostonese system been so deteriorated by years of exclusive and excessive bean diet as to be in-

Summer Health Resorts.

No people are so well off in the matter of health resorts of every variety, for both summer and winter, as those of the United States. We propose at this time to give a very general and comprehensive account of the resorts and mineral springs suitable for summer sojourn, omitting such as are in the far South and west of the Mississippi. Many of these are already well known to our readers, and the list which will be found in this number of the MEDICAL RECORD will serve chiefly as a reminder to physicians who may be thinking of recommending to their patients locations suited to their special summer needs.

In a general way, the summer health resorts may be divided into two classes: dry upland or mountainous regions, and lake or coast—the latter characterized chiefly by cool breezes, more or less moisture-laden. Unless one knows something of the peculiarities of the individual who is seeking health, rest, and recreation, it is impossible to advise a sojourn in either of these two classes, since, contrary to the prevailing idea, those affected with pulmonary and bronchial troubles are oftentimes benefited by a more or less extended residence upon the sea shore, with its cool breezes and more or less foggy atmosphere.

As a general rule, the low-lying and marshy area between tidewater and the uplands, all the way from Florida to New Jersey, is insalubrious, and more or less malarious during the summer months. There are, however, exceptional points to which this statement will not apply.

On the New Jersey coast there are a number of pleasant resorts, and as one goes farther to the north and east, this number increases very largely. The prevalence of fogs upon the sea-coast is largely influenced by the character of the shore, the indentations along it, and the country immediately behind it. Northward from New Jersey the shore line rapidly changes from low-lying, sandy beaches, with marshlands overflowed by the recurring tides, to the rocky shores of Connecticut and Massachusetts, and the bold bluffs and headlands of the coast of Maine, indented with bays of considerable magnitude, which are dotted with numerous islands, forming delightful places of retreat from the heat of summer. This entire shore is more or less subject to sea-fogs, and the air is heavily laden with moisture at all seasons of the year. Islands which are some distance from the mainland, strange as it may seem to some, are shown by observations of the weather, often to be drier than the mainland adjacent.

Fifty miles, or more, from the coast, in the vicinity of North Carolina, the foot-hills of the Appalachian chain begin, and there is a broad plateau, from six hundred to one thousand feet above the sea-level, covered with pitch pine, a region of exceptional healthfulness, particularly for those inclined to consumptive troubles. Such plateaux are found in New Jersey also, as, for example, at Schooley's Mountain, which is twelve hundred feet above the level of the sea. In New York, Vermont, and New Hampshire the altitude increases, and various groups of mountains, with heavily wooded plateaux, of from fifteen hundred to two thousand feet above the sea, occur, which are specially notable for the evenness of their temperature, and are famous as resorts of consumptives in winter as well as summer. New Hampshire is characterized by a somewhat cooler temperature than other States during the summer, as is also the State of Vermont, in consequence of the more general elevation of the land above the sea-level. The southern part of Rhode Island, on account of its insular position, is also a cool summer place of residence, which, with the facilities for sea-bathing, have done so much to give Newport and Narragansett Pier their reputation.

Maine.—Perhaps the best-known location in the State of Maine for summer residents is the Island of Mount Desert, in Frenchman's Bay, one hundred and ten miles east of Portland, and forty miles southeast of Bangor. The whole island is a mass of mountains, rising abruptly from the water, the highest two thousand feet above the sea-level. The hotels are numerous and good; the drives about the island are picturesque and beautiful. The principal village of Mount Desert is Bar Harbor. Somesville and Southwest Harbor are smaller hamlets on the opposite side of the island, quiet, delightful places. The temperature of Mount Desert is cool and bracing, although there are frequent fogs and considerable precipitation of water. Fires are often comfortable in midsummer. There are numerous places of popular resort between Bar Harbor and Portsmouth, N. H., upon the main coast, as Old Orchard Beach, Rye Beach, etc. The interior of the State is considerably elevated above tidewater, with broken, detached mountain peaks, and mostly densely wooded; Mount Katahdin, Moosehead Lake, Lake Moosemaguntick, are cool, picturesque, wild localities with good hotels.

At South Poland, Me., are the famous Poland Springs. Poland Springs House, is one of the best hotels in the country, very large and furnished with every modern appliance for comfort and recreation.

Off the coast of New Hampshire are the delightful Isles of Shoals, excellent places for quiet comfortable rest, fishing, and sailing. Of the White Mountains lying within this State, the climatic character is generally well known to the profession. At the principal points among the mountains are large and excellently appointed hotels

"DR. COMBES SANITARIUM."

A private home for the treatment of Mental and Nervous Diseases, situated at Woodhaven, L. I., only one mile from city; cars every ten minutes. Address R. C. F. COMBES, M.D., or M.D., Medical Supt., Woodhaven, L. I. Telephone 7, I., East New York.

WALNUT LODGE HOSPITAL,

Hartford, Conn.

Organized in 1880 for the special medical treatment of ALCOHOL AND OPIUM INEBRIATES. Elegantly situated in the suburbs of the city, with every appointment and appliance for the treatment of this class of cases, including Turkish, Russian, Roman, Saline, and Medicated Baths. This institution is founded on the well-recognized fact that inebriety is a disease, and curable, and all these cases require rest, change of thought and living, in the best surroundings, etc., etc.

Applications should be addressed

T. D. CROTHERS, M.D.,
Sup't Walnut Lodge, Hartford, Conn.

LONG ISLAND HOME,

A PRIVATE HOME FOR THE CARE AND TREATMENT OF MENTAL AND NERVOUS DISEASES.

Located at Amityville, Long Island, on Great South Bay, one hour from New York and Brooklyn. Applications can be made to the Medical Superintendent at the Home.

DR. J. E. BOWMAN,
Medical Superintendent.

Telephone Babylon, 14 B.

THE WINYAH SANITARIUM, ASHEVILLE, N. C.

(Special Institution for Affections of Lungs and Throat.)

A refined home, accommodating a limited number of patients and their friends. Every hygienic and other appointments for perfect care and comfort. Open all the year. Cool Summer and moderate Winter. Climate dry, pure atmosphere. No hopelessly advanced or offensive patients admitted. For particulars, address

KARL VON RUCK, M.D.

RICHLAWN.

A private home for the special care and medical treatment of ALCOHOL AND OPIUM INEBRIATES AND NERVOUS DISEASES. It is situated in a park of 13 acres, at SEA CLIFF, Queens Co., Long Island (one hour from New York). Address

H. L. RICHARDSON, M.D., Superintendent,
Sea Cliff, L. I., N. Y.

Or, can be seen in person, Mondays and Fridays, between 12 and 2 o'clock, P.M., at his office, 79 Washington Place, N. Y. City.

WALDEMERE ON-THE-SOUND,

Mamaroneck, N. Y.

For the private care and treatment of Mental and Nervous Diseases, Alcoholic and Narcotic Habitués. Waldemere is twenty miles from Grand Central Station, New York City. Trains every hour. Applications can be made at 5 E. 41st St., New York City, 9 to 11 A.M.

DR. E. N. CARPENTER, Superintendent.

OXFORD RETREAT.

A Private Institution for the Treatment of Insanity, Nervous Disorders, Inebriety, and Opium Habit.

Facilities and advantages are unsurpassed for the proper care and treatment of all forms of the above-named disorders. Attention is given to the proper classification of patients. Careful supervision at all hours. Average, one attendant to every four patients. Every needed convenience and any accommodations that may be desired. Retired and home like. Site elevated, beautiful, and salubrious. 39 miles from Cincinnati, 84 miles from Indianapolis; 8 trains daily. Terms moderate. For references, terms, etc., address G. F. COOK, M.D., Supt., Oxford, Butler Co., Ohio.

Send for a Catalogue of WM. WOOD & CO.'S Publications.

THE GLEN SPRINGS SANITARIUM.

MEDICAL FACULTY:

E. D. LEFFINGWELL, M.D., Pres. JAMES E. KING, M.D., Vice Pres. and Medical Sup't.
CHARLES HUNTER, M.D., Sec. E. GOULD WOODRUFF, M.D., House Physician.
MIRIAM GARDNER, M.D., Lady Physician.

Under the medical management of experienced physicians.

Located on a bluff, overlooking thirty miles of Seneca Lake, surrounded by Pine Forests, and near the famous Watkins Glen.

Equipped with all the most approved therapeutic appliances, including Turkish, Russian, Roman, Electric, Electro-thermal, Moliere, Saline, and Iron Baths.

Also Massage, Swedish Movements, Vacuum Treatment, Calisthenics, and all forms of Electricity.

Pure water—also valuable mineral springs, including Saline, Iron, Iodine, and Sulphur waters.

No Malaria. Pure air.

Climate mild, dry, and equable. More days of sunshine and less humidity than any other section of New York State. Beautiful views, charming walks and drives.

Modern improvements: Elevator, Electric Bells, etc. Cuisine unsurpassed.

Persons suffering from Tuberculosis, or from any other Contagious Disease; Epileptics, and persons afflicted with any form of Insanity, are not received For terms and illustrated pamphlet, address

WM. E. LEFFINGWELL, Manager,
Please mention MEDICAL RECORD. *WATKINS, NEW YORK.*

THE BELMONT,

Asheville, N. C., "The Land of the Sky."

The finest health resort in America. Located in a mountain grove of 65 acres, 2,500 feet above sea level. Delightfully cool in mid-summer; comfortably warm to sit out of doors in mid-winter. We have three fine medicinal springs (Iron, White and Black Sulphur) which possess remarkable curative properties. The best medical authorities pronounce the climate of Asheville the finest in the world for diseases of the throat and lungs. While the "Koch Treatment" is in its infancy, yet we are having excellent results in incipient cases. The skilled administration of tuberculin, combined with the climatic advantages of our location, is proving eminently satisfactory to our patrons. Accommodations first class. Terms reasonable. Take our private electric car at the depot for "The Belmont." Address

JOHN S. MARSHALL, M.D., Director.
KARL VON RUCK, M.D., Consultant. Please mention MEDICAL RECORD.

THE INEBRIATES' HOME, FORT HAMILTON, N. Y.

INCORPORATED 1866.

A Hospital for the Treatment of ALCOHOLISM and the OPIUM HABIT.

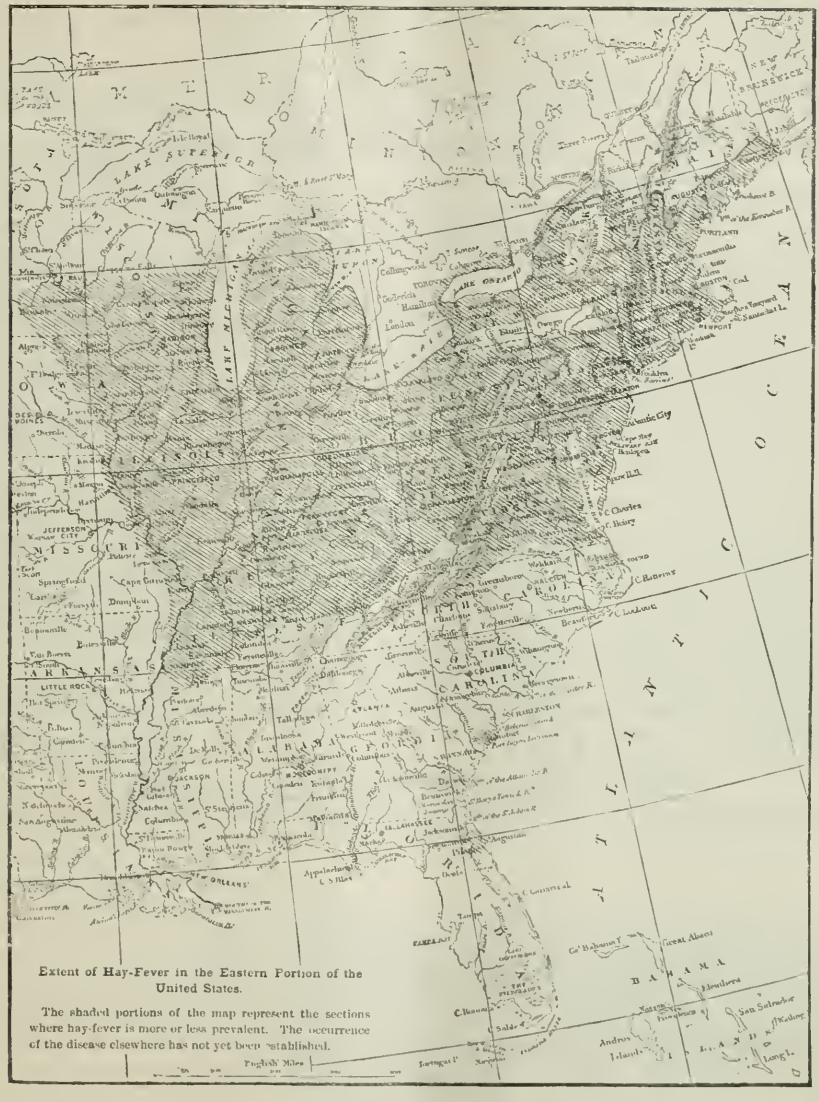
President Hon. G. G. HERMAN. Consulting Physician: L. D. MASON, M.D.
Medical Superintendent: JAMES A. BLANCHARD, M.D.

The building is situated in a park of twenty-six acres, overlooking and commanding fine views of the narrows, and the upper bay of New York Harbor.

The accommodations, table, attendance, and nursing are of the best character and suited to first-class patients.

For manner and terms of admission, apply to the Superintendent, at the Institution, Fort Hamilton (L. I.), N. Y

Please mention MEDICAL RECORD.



Extent of Hay-Fever in the Eastern Portion of the United States.

The shaded portions of the map represent the sections where hay-fever is more or less prevalent. The occurrence of the disease elsewhere has not yet been established.

while scattered about in the valleys are innumerable smaller hostelries, much used by those who desire to avail themselves of the advantages offered by this high plateau, at moderate and very reasonable charges. Here, and among the Green Mountains of Vermont, those who are afflicted with hay asthma find complete immunity, the little village of Bethlehem, N. H., especially being a Mecca for this class of unfortunates, much thronged during August and September. By reference to the map here appended the regions of the entire United States which are said to be places of refuge for those who are liable to hay fever, may readily be seen. They include the White, Green, and Franconia Mountains, the northern part of the State of Maine, the Adirondack region, the southern section of New York, as far west as Lake Erie, and the crests of the Alleghanies. Of the great part of the country west of the Mississippi little is known in relation to its exemption from this disease. Probably all regions of one thousand or more feet above the ocean, unless covered with rank vegetation, are likely to be free from hay fever.

In the State of Vermont we may direct special attention to the entire region of the Green Mountains and the Franconia Mountains. Mount Mansfield, the highest of the range, is four thousand three hundred and forty-eight feet high. In the northwest corner of the State, ten miles east of St. Albans, are the Sheldon Springs, four in number. They are alkaline, and are claimed to be of efficiency in the cure of cancer. The surroundings of the Village of Sheldon are delightful. In sight are many

PRIVATE HOSPITALS, SANITARIUMS AND RETREATS.

KENSETT.

For the care and treatment of Insanity and Nervous Diseases, Alcoholic and Narcotic Habitués. Address EDWIN EVERETT SMITH, M.D., South Wilton, Connecticut. Thursdays, 1.30 to 3.30 P.M., 44 West 36th Street, New York City.

MENTAL AND NERVOUS DISEASES.

DR. RALPH L. PARSONS

Receives cases of Mental and Nervous Diseases, for care and treatment, at his residence at **Greenmont-on-the-Hudson**, near the **Village of Sing Sing.** Inquiries may be addressed to Box 234, Sing Sing P. O., New York; or made in person on Mondays and Fridays, between 3.30 and 4.30 o'clock, P.M., at his office, No. 21 East 44th Street, New York City.

Private Hospital for Mental Diseases,

Comfort without care; freedom from the taxations of fashionable life and from the excitements and temptations of Summer resorts.

Especial provision for quiet and rest, also for recreation, amusement, and regular out-door life.

Telegraph, telephone, electric bells, safety elevator, and all modern appliances for comfort and health.

On direct line of Delaware, Lackawanna & Western R. R., between New York City and Buffalo. Only nine hours from New York.

OPEN ALL THE YEAR.

For circulars and other information, address

J. ARTHUR JACKSON, Cor. Secretary,

Dansville, Livingston Co., New York.

Formerly Jackson & Leffingwell.

Please mention MEDICAL RECORD.

of the summits of the Green Mountains. It is about two thousand feet above the sea. Congress Hall is an excellent hotel. At Alburg's Springs, on the shores of Lake Champlain, is an alkaline spring, containing an excess of sulphide of potassium. Its chief constituents are bi-carbonate of lithia, bi carbonate of magnesia, and bi-carbonate of lime. The Alburg Springs House is a comfortable place to stop at.

The eastern section of Massachusetts contains a number of popular summer resorts, situated upon its low, sandy beaches. Sea breezes are almost continuous throughout the summer, and keep the temperature at a comfortable point. The little villages scattered about on Cape Cod are full of boarding-houses which receive summer visitors at moderate rates. All the larger towns on the coast are cool and healthful places. Martha's Vineyard and Nantucket are both, from their insular positions, delightfully cool throughout the summer, and afford many attractions, especially Nantucket, for a quiet resting-place, far enough from the turmoil of the world. In the western part of the State are the Berkshire Hills, a section which has long been famous for its picturesque beauty, and invigorating, healthful atmos phere. Here are found Great Barrington, Stockbridge, Lenox, Pittsfield, and South and North Adams. Near Great Barrington are the Berkshire Soda Springs, said to contain chlorine, carbonic acid, soda, and alumina.

Block Island (Spring House), off Narragansett Bay, is a quiet retreat which is increasingly patronized, reached by daily steamers. Watch Hill, also in Rhode Island, near Stonington, is crowded with excellent summer hotels, among which the Larkin House stands pre-eminent, and, being upon a high point jutting out into the Sound, is almost always cool and pleasant. Of Newport and Narragansett Pier it is only necessary to speak. Accommodations may be had at either place to suit the purse of the traveller.

The south shore of Connecticut, bordering upon Long Island Sound, is an excellent place to escape the heat of summer, all of the towns and villages having excellent hotels, and some, especially intended for summer occupancy only, are found upon the points jutting out into the water. Among these may be mentioned the Indian Harbor House and the Lenox House at Greenwich, handsome buildings immediately upon the water. Farther east are the towns of Stamford, with Shippan Point adjacent (Ocean House), Fairfield, which has a magnificent sandy beach, and one of the best harbors on the coast, at Black Rock. Then come Stratford, Milford, and West Haven. Further eastward the shore is not so picturesque, but has, nevertheless, a number of popular resorts. At the mouth of the Thames River, near New London, is the celebrated Pequod House, one of the most fashionable summer places along the shore, and on the opposite side of the river is the Fort Griswold House. The State of New York is particularly rich in summer resorts, from the sandy sea coast of Long Island to the densely wooded Catskills and Adirondacks, and the mineral springs so numerously scattered throughout the State. The south shore of Long Island is low and sandy, and protected for sixty miles of its western portion by an outlying bar, enclosing several large bays, chief of which is Great South Bay. After passing the eastern extremity of Shinnecock Bay, the ocean breaks immediately upon the shore of the island for the remaining thirty miles of its length. Statistics which appear to be reliable have been published, showing that in this latter section no case of malaria has ever been recorded. The water is particularly pure and clear. No mineral springs exist on the island. The north shore of the island is in the main rocky, and more or less elevated above the water. It does not possess the refreshing coolness which the breezes coming directly from the ocean bring to the residents of the southern shore.

At the extreme eastern end of Long Island, in Peconic Bay, is Shelter Island (Manhanset House) which is a pleasant place of rest, opposite Greenport, a quiet little village, having pleasant drives.

Among the mountains on the west shore of the Hudson River, the Shawanguck and the Catskills contain many delightful places of escape from the heats of other sections. For those who like the society of refined and Christian people, no better stopping places can be found than the hotels kept by the Smiley Brothers, at Lake Mohonk (Lake Mohonk House) and Lake Minnewaska.

Saratoga is hardly a place a physician would advise his patients to spend the summer at, except for such benefit as he might wish them to derive from the drinking of its waters. Its hotels are magnificent, and it has some most delightful drives. It is crowded with fashionable people. Those who can obtain pleasure chiefly from association with other people can find no better place perhaps than Saratoga Springs. The waters of its springs have been frequently analyzed, and most of them are on record. We will be pleased to supply to any physician who desires it the analysis of any special spring, if it has been made, on application.

The Adirondack region has long been celebrated for its healthfulness, many of our best physicians claiming that, especially for those with pulmonary troubles, it is an all-year-round place of residence, its high altitude and its wooded character seeming to produce an atmosphere especially beneficial to those in the early stages of such troubles. Here, too, as we have already noted, immunity may be had from the distressing conditions of hay-fever. It is almost crowded with small lakes of the purest water, and it is generally upon the shores of these lakes that the hotels are situated and that camps are formed.

Not all of the mineral springs of the State are situated in localities which are especially pleasant for summer outing, some of them being in the vicinity of large towns or cities. Others are more favorably located, in the midst of rural scenes and away from the disturbances of urban places.

To the southwest of Saratoga are the Ballston Springs, possessing very nearly the same properties as those of Saratoga. The only warm springs in the State of New York are situated at Lebanon, Columbia County, N. Y., temperature 73° F. The water is principally used for bathing.

Sharon Springs, in Schoharie County, N. Y., are sulphur and magnesia waters. In this section are delightful rides, through Cherry Valley, Cooperstown, and in other directions. Cooperstown itself is a most healthful and pleasant place in which to pass the heated term.

Richfield Springs, Otsego County, N. Y., at the head of

PRIVATE HOSPITALS, SANITARIUMS AND RETREATS.

Hours: 9 to 12 A. M., and by appointment.

Parrish's Home for Invalids,

At BURLINGTON, NEW JERSEY.

Founded by JOSEPH PARRISH, M.D.
WILLIAM G. PARRISH, M.D., Proprietor, and personally in charge.
S. J. HOLLEY, M.D., Assistant.

This is emphatically a family home, with the privacy and freedom of domestic life, the patients being under the counsel and guidance of experienced physicians may often avoid the alternative of commitment to a public asylum or hospital.

Disappointment, loss of property, grief, mental strain and worry, overwork, excess in the use of stimulants and narcotics, hysteria, are frequently associated with, or complicated by, Neuralgia, Rheumatism, Gout, Dyspepsia, and even Lung troubles, for all of which appliances are available, in the way of Baths—Massage, Electricity, etc., and the *Oxygen Treatment*, the value of which in incipient Throat and Lung Diseases is generally conceded.

An attractive feature of the Home treatment is the removal of the family during the summer to a country seat in the vicinity, or to the seaside, mountains, or other resort, accompanied by the superintendent and staff.

Terms are arranged with, or for each person according to circumstances and requirements. For further information, call on or address WM. G. PARRISH, M.D., Burlington, N. J.

Please mention MEDICAL RECORD.

ESTABLISHED 1855.

DR. STRONG'S SANITARIUM,

SARATOGA SPRINGS, NEW YORK.

Receives persons recommended to it by their home physicians for TREATMENT, CHANGE, REST, OR RECREATION, And places them under well-regulated hygienic conditions so helpful in the treatment of chronic invalids or the overtaxed.

For Treatment: In addition to the ordinary remedial agents, it has a Sun Parlor and Promenade on the roof. Turkish, Russian, Roman, Sulphur, Electro-Thermal, the French Douche, and all Hydropathic Baths; Vacuum Treatment, Swedish Movements, Massage, Pneumatic Cabinet, Inhalations of Medicated, Compressed, and Rarefied Air, Electricity in various forms, Thermo-Cautery, Calisthenics, and Saratoga Waters, under the direction of a staff of educated physicians.

For Change: This Institution is located in a phenomenally dry, tonic, and quiet atmosphere, in the lower arc of the Adiroudack zone, and within the "Snow Belt."

For Rest: The Institution offers a well-regulated, quiet home, with elevator, electric bells, open fire-places, steam, and thorough ventilation. With cheering influences and avoiding the depressing atmosphere of invalidism.

For Recreation: To prevent introspection, are household sports at all seasons of the year, and in Winter tobogganing, elegant sleighing, etc.; in Summer, croquet, lawn-tennis, etc.

Private professional references furnished upon application. Physicians are invited to inspect the Institution at their convenience. A liberal discount to physicians and their families for board or treatment. Send for illustrated circular. Address

Please mention MEDICAL RECORD. DR. S. E. STRONG, THE SANITARIUM, 90 Circular St.

Schuyler's Lake, forms one of the chief attractions to visitors. Its principal ingredients are sulphate of magnesia and sulphate of lime.

Clifton Springs, in Ontario County, N. Y., are celebrated for their beneficial effects in bilious troubles and skin disorders. The waters are strongly impregnated with the sulphates of lime and magnesia, somewhat similar to the Greenbrier Springs of Virginia. The climate is salubrious and the place quite fashionable.

One of the most delightful and healthful resorts of Western New York is the Jackson Sanitarium, at Dansville, Livingston County. Not far from here are the Warsaw Salt Baths and Sanitarium, at Warsaw, Wyoming County; heavily laden brine, from wells fourteen hundred to two thousand feet deep, afford an inexhaustible supply of pure salt water for bathing purposes.

The building of the Jackson Sanitarium, which is very large, is situated upon the side of the hill twelve hundred feet above sea level, and commands a magnificent view of the beautiful Genesee Valley. Every comfort, combined with professional attendance, may be had here.

Chittenango Springs, in Madison County, are situated in the narrow and romantic valley of Chittenango Creek, a little over a mile from the village. The surroundings are extremely romantic and well worth visiting. White Sulphur Springs Hotel is a first-class house. The waters are usually taken before meals, and belong to the calcic class.

Chautauqua Lake is a beautiful body of water, surrounded by hills six hundred or seven hundred feet in height, affording attractive views. Jamestown is the southern end and outlet of the lake. Chautauqua, a little farther up, is well known throughout the country as the annual meeting-place of the National Sunday School Association and the Chautauqua Literary and Scientific Circle. Excellent hotels may be found scattered about on both sides of the lake.

New Jersey.—The northern part of New Jersey is broken by rugged mountains, interspersed with beautiful valleys and streams, filled with fish.

Schooley's Mountain, already referred to, is not far from the City of New York, and is about twelve hundred feet high. On the west side of the mountain is a mineral spring containing muriate of soda and lime, etc., beneficial in dyspepsia and bladder troubles. There are two excellent hotels, the Heath House and Belmont Hall.

Atlantic City is at the present day the most popular seaside resort in this State. It has very numerous hotels and boarding-houses of all kinds.

Cape May, at the southern extremity of the State, is almost insular in its surroundings, with the waters of the Atlantic on one side, the Delaware Bay on the other. Cool breezes prevail throughout the summer. The hotels are numerous and good.

Beach Haven is situated upon a sand bar, with Little Egg Harbor on one side and the ocean on the other. It is six miles from the mainland. Hay fever is said to be unknown. There are good hotels, and many fine cottages.

Further up the coast are the well-known seaside resorts, Asbury Park, Ocean Grove, Seabright, and Long Branch.

Pennsylvania.—Delaware Water Gap, situated at the passage of the Delaware River through the Kittatinny or Blue Mountains, is a favorite place of resort, and has numerous pleasant drives, as well as innumerable walks through the woods upon the mountains.

Mauch Chunk is situated among some of the wildest scenery in the country, and has much to make it attractive to the tourist.

Altoona, on the Pennsylvania Railroad, is surrounded by the wildest and most picturesque scenery. Its altitude is such as to give immunity from hay fever and asthma. The Logan House is first class in every particular.

Crescent Springs, Cambria County, is a delightful place, its mountain elevation being such as to prevent the heat from ever becoming oppressive, and the nights are always cool. The springs are seven in number, and contain iron, lime, and magnesia. The Mountain House is owned by the Pennsylvania Railroad Company, which does everything to make its guests enjoy themselves.

The purgative waters of Bedford Springs, in Bedford County, are considered especially valuable in cases of anæmia accompanied by excess of adipose tissue. They are always considered useful in enlargement of the liver. The diuretic effect of the water is said to be considerable.

Maryland.—In Maryland, a large and excellent hotel has been erected recently at Blue Mountain Station, in the Blue Ridge Mountains, Washington County (Blue Mountain House). Its altitude is great, and it is surrounded by very picturesque scenery.

Eastern Shore is not considered healthful during summer.

Virginia.—The position of Old Point Comfort, Va., is such as to make it a pleasant resort, both summer and winter. The hotel is very large, and the facilities for boating and bathing unexcelled. The rides are very attractive.

Virginia Beach, reached from Norfolk, has a very delightful hotel in the Princess Annie, with excellent seabathing.

It is in its mountain resorts and mineral springs, however, that Virginia and West Virginia most excel.

The White Sulphur Springs of West Virginia is the most famous watering-place of the Southern States, and its principal hotel, with its numerous cottages about, is a picture of itself. The waters of the spring contain purgative sulphates, salts of lime, and sulphurated hydrogen. They are aperient and alterative, with marked effects on the kidneys and liver. They are not only used internally, but for baths, both hot and cold. The altitude, of nearly two thousand feet above the sea, insures cool and refreshing air, and restful sleep at night.

The Old and Red Sweet, and Red Sulphur Springs, are sulphur waters producing a sedative effect when taken internally. They also act as cathartic and diuretic.

Bath Alum Springs are near the Warm Springs Mountain, five miles from the spring of the same name. The waters are tonic and astringent, and are indicated in cases of scrofula, dyspepsia, etc.

Rockbridge Alum Springs, in Rockbridge County, near the village of Goshen, are the most esteemed of the alum waters of Virginia; highly valued in cases of scrofula, chronic diarrhœa, leucorrhœa, and chronic eczema. The surrounding scenery is attractive and beautiful.

RICHFIELD SPRINGS, N. Y.

The New Bathing Establishment.

UNSURPASSED IN THE WORLD.

The American Dermatological Association passed the following unanimous vote: "It would place upon record its high appreciation of the very extensive and complete equipment provided in Mr. Proctor's establishment for its varied application in all classes of disease in which it has been shown to be beneficial. The medical profession in America may congratulate itself upon now having at home, under the control of so competent a proprietor, baths which are not surpassed in adaptation to its purposes by any in Europe."

In this journal of May 2, 1891, Dr. Kelly writes: "As an instance worthy of emulation, I may mention the new bath-house and its appurtenances at Richfield Springs, N. Y. In adaptability of architectural design, in arrangement and variety of its baths, and in scientific facilities for the therapeutic employment of the waters, I commend it as a model up to date. Withal, a competent resident physician is in charge, with an office in the bath-house, in complete supervision of all therapeutic measures which the place affords.

DR. C. C. RANSOM, 56 W. 49th St., New York, Physician in Charge.

WILLARD LESTER, Manager.

Please mention MEDICAL RECORD.

In corresponding with Advertisers please mention MEDICAL RECORD.

The Berkeley Springs, in Morgan County, W. Va., are chiefly used for baths. They are thermal waters. Every facility is provided for bathing and swimming. It is one of the most fashionable and popular resorts in the country, as is also Capon Springs, on North Mountain, W. Va., the Capon water, containing silicic acid. magnesia, soda. bromine, iodine, and carbonic acid gas, recommended for affections of the nervous system.

The Bedford Alum Springs are somewhat similar in character to the waters of the Rockbridge Alum Springs, and are decidedly useful in all anæmic conditions.

The Buffalo Springs of Mecklenburg County are of great value in inflammation and irritation of the bladder and kidneys. Immense quantities of the water are bottled and transported to all sections of the country. They are endorsed by the highest medical authorities.

The western section of North Carolina consists of high table-lands, with lofty ranges of mountains. The climate at all seasons of the year is salubrious, the temperature being very equable. Asheville is a thriving place, situated in the valley of the French Broad River, and surrounded by mountains. There are white sulphur springs in the vicinity of the town, and beautiful drives in every direction—a delightful place to spend several weeks.

In Michigan, Grouse Isle, Saginaw Bay, and Mackinac Island are places of considerable popularity, and much frequented during the heated term.

The St. Louis Mineral Springs, in Gratiot County, are strongly alkaline, with traces of iron, and some of the salts of lime; said to be useful in cases of dyspepsia and neuralgia. They are situated in the midst of pine forests.

Devil's Lake, Lake Geneva, and Waukesha are much resorted to in the State of Wisconsin.

Among the Western Catskills, at Stamford, is Churchhill Hall, eighteen hundred feet above tidewater. It has all the advantages of dry, bracing mountain air, and every comfort.

A most delightful place to spend a few weeks is Penobscot Bay, in Maine, at the Ilesboro Inn.

Adirondacks.—The number of heathful and pleasant places scattered about in this region is very large. Among those best known are Blue Mountain Lake (Prospect House), the Lower Saranacs (Hotel Ampersand), Paul Smith's.

Not far from New York, in Orange County, is Greenwood Lake, a very beautiful, narrow body of water, enclosed by rugged mountains, with clear, deep waters, which abound in black bass.

Helderburg Mountains, not far from Albany, are becoming a favorite place of resort. The commanding views of the mountains of Massachusetts, Vermont and Northern New York, are very attractive.

For those who desire to spend some time upon fresh water, among the most attractive and romantic scenery possible, the Thousand Islands of the St. Lawrence, and Alexandria Bay, offer attractions which are not to be surpassed. The Thousand Island House at the latter place is an excellent hotel.

The region about Lake George has many resorts, both fashionable and more quiet, which extend many attractions, in the form of pure mountain air combined with excellent boating and fishing.

Trenton Falls, on West Canada Creek, north of Utica, is an exceedingly romantic place, surrounded by mountains and forests.

Watkins Glen, near the village of Watkins, is one of the most delightful places to spend a few weeks in the State, with numerous excellent hotels.

HOTEL WESTPORT,

Platt's Chlorides,

The True Disinfectant.

Eleven years of practical daily use, by tens of thousands of intelligent physicians, and by hundreds of thousands of careful housekeepers, has established beyond doubt the value, the usefulness, and the superiority of Platt's Chlorides.

An odorless liquid, clean, stainless, powerful, efficient, and economical, it is peculiarly adapted to all the sanitary needs of the sick-room, and the hygienic demands of the household.

Platt's Clorides is sold in quart bottles only, and by nearly every apothecary in every city, town, or village in the United States. Should there be any practising physician anywhere who may not, as yet, personally know its value, a sample, with descriptive circulars, etc., will be gladly furnished free.

Address, giving both Post and Express Offices,

HENRY B. PLATT, 36 Platt Street, New York.

Please mention MEDICAL RECORD.

RESTORATIVE WINE OF COCA.

For Nervous Prostration, Brain Exhaustion, Neurasthenia, and all forms of Mental and Physical Debility.

This WINE OF COCA is so prepared that it contains the active principle of the leaves in a perfectly pure form. Moreover, it is absolutely free from all those foreign substances which all other wines of coca contain, and which interfere, to a great extent, with its curative influence. It is well known that the cocaine contained in the coca-leaves varies considerably in its proportion; hence, giving to the wines as ordinarily made, uncertain strength, and causing them to be unreliable in their action on the system. In the RESTORATIVE WINE OF COCA the proportion of alkaloid is invariable, and the physician can, therefore, prescribe it with the certainty of obtaining uniform results.

Prof. WM. A. HAMMOND, M.D., says: A winegiassful of this tonic, taken when one is exhausted and worn out, acts as a most excellent restorative; it gives a feeling of rest and relief. **I have discarded other wines of coca and use this alone.** It produces also excellent results in cases of depression of spirits; in hysteria, headache, and in nervous troubles generally it works admirably. It is a simple remedy, yet efficacious and remarkable in its results.

FEBRICIDE.

A Complete Antipyretic, a Restorative of the Highest Order, and an Anodyne of Great Curative Power.

"Febricide" will be found to be possessed of great curative power in Malarial Affections of any kind, and in all inflammatory disease of which Fever is an accompaniment. **For Neuralgia, Muscular Pains, and Sick Headache, it is a Specific.**

Prof. WM. F. WAUGH, M.D., of Philadelphia, writes: In a case of persistent neuralgic headache, worse on awakening, with a possibility of malaria, "Febricide" gave instant relief.

Trenton, N. J., February 22, 1890.

February 12, I was called to visit a young man aged 22 years, suffering from headache and Malarial Neuralgia. I commenced at once giving the FEBRICIDE PILLS, one every three hours, taking in all, eighteen pills. He was cured in three days and his sleep at night was sound and refreshing, which had not been the case before taking the pills.
WM. H. VAN DUYN, A.M., M.D.

New Lisbon, Ohio, Sept. 8, 1890.

I find FEBRICIDE an excellent remedy in reducing temperature in Fever, Rheumatism, and acute trouble generally, at the same time sustaining the patient. I know of no other combination in acute Rheumatism than a FEBRICIDE PILL, together with four of five grains of Soda Salicylate given every three to six hours. By such combination the pain is relieved with amazing rapidity, fever abates, and the disease is cut short at once.
TOM. H. MARQUIS, M.D.

SPRINGVIEW, NEB., November 25, 1889.

I have used your FEBRICIDE with excellent results in our Mountain Fevers (typhoid), reducing, in one case, the temperature from 104⅘ with dry, brown furried tongue in ten hours, to 99⅘ with tongue cleaning promptly and moist, and rapid improvement dating therefrom. Have used Antipyrin in similar cases with no good results.
ALBERT S. WARNER, M.D.

NATROLITHIC SALT.

Containing Sulphate of Soda, Carbonate of Soda, Phosphate of Soda, Chloride of Sodium, Sulphate of Lime, Sulphate of Magnesia, and Carbonate of Lithia. For Habitual Constipation, Rheumatic and Gouty Affections, Biliousness, Corpulence, Dyspepsia, and all Derangements of the Digestive Tract, it is a wonderful remedy. *Does not gripe after administration.*

Samples will be sent free of charge to any Physician who mentions MEDICAL RECORD.

HEALTH RESTORATIVE CO., 90 South 5th Ave., NEW YORK.

ESTABLISHED 16 YEARS. BEWARE OF IMITATIONS.

COLDEN'S LIQUID BEEF TONIC

AN INVALUABLE AID IN MEDICAL PRACTICE.

ORIGINAL | COLDEN'S LIEBIG'S LIQUID EXTRACT OF BEEF AND TONIC INVIGORATOR. | LABEL.

Essentially Different from all other Beef Tonics. Universally Endorsed by Leading Physicians.

This preparation, consisting of the Extract of Beef (prepared by Baron Liebig's process), the best Brandy obtainable, soluble Citrate of Iron, Cinchona, and Gentian is offered to the Medical Profession upon its own merits. It is of inestimable value in the treatment of **Debility, Convalescence from Severe Illness, Anæmia, Malarial Fever, Chlorosis, Incipient Consumption, Nervous Weakness,** and maladies requiring a Tonic and Nutrient. It is quickly absorbed by the Stomach and upper portion of the Alimentary Canal, and therefore finds its way into the circulation quite rapidly.

COLDEN'S LIQUID BEEF TONIC appeals to the judgment of intelligent Physicians in the treatment of

ALL CASES OF GENERAL DEBILITY.

By the urgent request of several eminent members of the medical profession, I have added to each wineglassful of this preparation two grains of Soluble Citrate of Iron, and which is designated on the label "**With Iron, No. 1**"; while the same preparation **Without Iron,** is designated on the label as "**No. 2.**"

In prescribing this preparation, physicians should be particular to mention "*COLDEN'S,*" viz., "*Ext. Carnis Fl. Comp. (Colden).*" A Sample of **COLDEN'S BEEF TONIC** will be sent free on application, to any physician (enclosing business card) in the United States. *Sold by druggists generally.*

C. N. CRITTENTON, General Agent, 115 Fulton Street, New York.

GLENN'S SULPHUR SOAP BEWARE OF COUNTERFEITS.

Physicians know the great value of the local use of Sulphur in the **Treatment of Diseases of the Skin.**

CONSTANTINE'S PINE TAR SOAP THE BEST SOAP MADE.

Has been on trial among physicians for very many years as a healing agent. **By far the Best Tar Soap made.**

Wholesale Depot, C. N. CRITTENTON, 115 Fulton Street, New York.

Samples of above Soaps SENT FREE, on application, to any Physician enclosing card. Please mention MEDICAL RECORD

OF INTEREST TO ALL MEDICAL PRACTITIONERS.

WHY "**MUMM**" IS SO POPULAR WITH PHYSICIANS.

G. H. MUMM & CO.'S EXTRA DRY is recommended for its purity, its small amount of Alcohol, and its wholesomness by such eminent physicians as :

Dr. D. Hayes Agnew, Thos. G. Morton, Wm. H. Pancost, - *PHILADELPHIA.*
" Fordyce Barker, Lewis A. Sayre, Wm. H. Thomson, - *NEW YORK.*
" Alan P. Smith, H. P. C. Wilson, - - - - - *BALTIMORE.*
" J. Mills Browne, *Surgeon-General U. S. Navy;* John B. Hamilton, *Supervising Surgeon-General, Marine Hospital Service;* Wm. A. Hammond, Nathan S. Lincoln, - *WASHINGTON.*
" H. Byford, Chr. Fenger, R. Jackson, C. T. Parkes, E. Schmidt, *CHICAGO.*
" A. C. Bernays, W. F. Kier, H. H. Mudd, - - - *ST. LOUIS.*
" A. L. Carson, James T. Whittaker, - - - - *CINCINNATI.*
" Stanford E. C. Chaille, Joseph Jones, A. W. de Roaldes, *NEW ORLEANS.*
" C. B. Brigham, R. B. Cole, Levi C. Lane, J. Rosenstirn, *SAN FRANCISCO.*

"Having occasion to investigate the question of wholesome beverages, I have made a chemical analysis of the most prominent brands of Champagne. I find G. H. Mumm & Co 's Extra Dry to contain, in a marked degree, less alcohol than the others. I therefore most cordially commend it, not only for its purity, but as the most wholesome of the Champagnes."—R. OGDEN DOREMUS, M.D., *Professor of Chemistry, Bellevue Hospital Medical College, New York.*

No Openers required. FOR USE IN SICK ROOMS and families. By a recent and most practicable invention no openers in future will be required for G. H. Mumm & Co.'s Champagne. To break the wire—bring the small seal to a horizontal position, and bend from side to side till one of the wires is broken, pulling upward removes top of cap and wire—done in an instant.

The 1884 vintage has been unexcelled in years, and Messrs. G. H. Mumm & Co secured large quantities of it. Of the 1887 and 1889 vintages, worthy successors to the 1884, Messrs. G. H. Mumm & Co. also bought immense quantities, they making it a rule to lay in sufficient stock of fine vintages to tide over the poorer ones, which accounts for the uniformity and excellence of their justly celebrated Extra Dry, and enables them to supply all demands, while maintaining the same high character of their wine. Please mention MEDICAL RECORD.

capable of resisting other forms of animal, vegetable, and mineral food? 2. Does the Massachusetts lobster, in its natural state, contain the deadly poison; or is the arsenic to be looked for in the food and drink which the animal takes into its stomach. As regards the first question, investigation so far has disclosed the fact that not one of the jurymen had ever resided out of view of the State-House dome, and all had the proper reverence for the Common, Commonwealth Avenue, and the Common Council.

In determining the second point some difficulty was encountered. It was contended that the natural bright red color of the lobster was one scarcely to be obtained without the use of arsenic. This was convincing, and had almost caused a vote that the lobster was a *sui juris* arsenic-bearing crustacean, when a gentleman from Denver suggested that the natural hue of the Colorado lobster was green. This created an animated discussion, and though a Boston poet was quoted to the effect that the lobster was the cardinal of the sea, it was finally admitted that Western lobsters might be verdant, but that, if they were, and it was not due to their environment, it must be attributed to Paris green.

Some one asked if the cans had been examined for ptomaïnes, but this was promptly ruled out of order. An element of doubt was thrown upon the whole matter by the evidence of a chemist, who testified that as he was long-lost treatise on Hindoo medicine with a specimen of wall-is extensively quoted in all standard works on Hindoo medicine. The editor, a distinguished native physician of Shar Beri, in the remote district of Rohtak, in the Punjab, says that he could not procure a complete manuscript anywhere, but had to work on odd chapters from different families of Vaidyas in India.

HOSPITAL MANAGEMENT.

The question of the most satisfactory method of organizing and managing a hospital has been exciting much attention of late. The difficulties or formalities attending the admission of critical cases have led to some adverse criticism of existing systems. The resignation of an entire house-staff on account, it is said, of the arbitrary conduct of the superintendent has also contributed to the timeliness of a discussion on this subject. One of the daily papers has told its readers editorially that hospital superintendents ought always to be doctors. "All the questions," says the *World*, "with which he is called upon to deal require the expert judgment of an experienced physician. Even the business management of a hospital has for its object medical and surgical results, and a layman at the head of such an institution is scarcely less out of place than a surgeon would be in control of a bank or a clergyman at the head of a railroad system."

We must confess that we do not agree with the *World* on this point. There can be no definite rule laid down, save this, that a hospital superintendent should be a man of tact, knowledge, and executive skill. If he is also a doctor this may be an advantage. Roosevelt Hospital never had a better superintendent than the late Dr. Paine. On the other hand, Bellevue Hospital never had a better superintendent than its late warden, Mr. Fallon, a gentleman who came to the institution with no special knowledge of hospital management. It is the right man and not his profession that hospitals need, and sometimes boards of governors are very stupid in their selections. Medical co-operation is particularly needed in this respect, for it is the physicians who are quickest to see the merits or weaknesses in the general business management of the hospital.

It is impossible in this connection not to refer to the gross injustice, both to hospital and profession, brought about by the establishment of rules which prevent the election of medical men to seats on the governing board. This rule, which, as is well known, prevails in some New York hospitals, is a standing affront to the physicians and tends to lessen the feeling of sympathy and desire for co-operation which should exist between the medical and the governing bodies.

OUGHT MEDICAL WOMEN TO MARRY?

The momentous question as to how many trained nurses marry has been investigated and settled in England, to the satisfaction, we trust, of the trained nurse, who is found to be the most marrying of all classes. And now the important topic of whether medical women should marry has been agitating the press of New York. A large number of interviews with medical women have been published with results which are not particularly surprising or fruitful. So far as one can gather from the mazes of femine periphrases, those who have married think that lady doctors can marry, conduct a household, and raise children as well as practise a profession. On the other hand, those who have not married express somewhat contrary views.

It is a little unfortunate that a subject of so much importance has not been flooded with a more searching and vivid luminosity. It looks very much as though every one would have to work the problem for himself.

In dealing with a question which involves so much of human passion and romance, it is necessary for the scientific student to put the curb on at once and get down to basic principles. One of these principles is that an attractive woman is bound to get married whatever be her aspirations or profession. We tender *ex animo* the compliment to our medical sisters of adding that the majority do get married.

It is the fact, then, that most medical women, being attractive and interesting personalities, become wives and mothers. The question is now, therefore, ought they to do it?

We are obliged to say that we do not think they ought. The physician's work is most arduous and exacting. It calls not only for physical toil, but for study, anxiety, the constant attempt at perfecting present skill and adding new accomplishments. This cannot be done fairly and well if the woman bears and raises children. The medical woman should marry only if she can consent to a childless union; or perhaps if she devote herself to some narrow specialty, that makes only short and specific demands on her time.

We are quite aware that there are some brilliant examples of married medical women who have proved themselves devoted wives and mothers as well as skilful practitioners. We generally receive from some of them letters of a didactic and chastening character when we

venture to express opinions upon the subjects of the nature of that we are now discussing. Such letters we always gladly publish, on account of the subtle interest which is always attached to the attempts of woman to reason clearly and dispassionately. Our columns are open still, for some time we think they can do it.

News of the Week.

The Late Dr. Fordyce Barker.—At a meeting of the Medical Board of Bellevue Hospital, held June 1, 1891, the following resolutions were adopted:

Resolved, That it is with the deepest sentiments of regret that this Board has learned of the death of Fordyce Barker, M.D., LL.D., who has been identified for so many years with the medical staff of this hospital as one of its most distinguished and deservedly esteemed members; that his removal at this time is felt by his colleagues as a special loss to the institution.

Resolved, That in Dr. Barker his colleagues have always recognized a man of exceptional endowments both of mind and education, which made him the ornament and pride of medicine, and which caused him to be an example in these respects to all his fellows.

Resolved, That the thirty-five years spent in ministering to the sick in this hospital with the faithfulness to that duty which characterized Dr. Barker, is of itself a testimony to the worth of the life which is now closed. But in addition to this Dr. Barker used the opportunities of his connection with this hospital to teach others by his experience, by his wide knowledge, by his exceptional skill, and by his great literary gifts, to an extent which has been widely appreciated by the whole medical profession in America and abroad.

GEORGE WOOLSEY, M.D.,
Secretary Medical Board.

The Title of Dr. Grandin's Paper.—Dr. E. H. Grandin writes: "Through an error on the part of your stenographer the title of the paper which I read before the Academy of Medicine is stated to have been 'Is Embryotomy of the Living Fœtus Ever Justifiable?' (MEDICAL RECORD, June 13, 1891, page 689). Since I have never claimed, and would never claim, that there are no conditions under which embryotomy will not find justification, and since the correct title of my paper, as taken from my manuscript, occurs on page 641 of your previous issue, kindly do me the favor to state that the word 'ever' does not, and did not, belong in the title of the paper."

The German Poliklinik took formal possession of its new home, No. 78 East Seventh Street, on Sunday, the 14th inst., at which time it was open for inspection by its many friends and patrons. The institution, which was founded in 1883 by seventeen physicians, was located in Sixth Street. The overcrowding of the Poliklinik with the poor, who always found ready hands there to help their ailments, made it a necessity for the trustees to look for a more spacious home. With the help of a few yearly benefit performances and the recently-formed Ladies' Auxiliary Society of the German Poliklinik the trustees felt enabled to purchase the above house. The building, which has been especially adapted for the purpose, answers all the requirements in regard to sanitary condition. Each department has its commodious quarters with all the necessary implements attached. There are spacious waiting-rooms, a drug store, an assembly-room for the medical staff, etc.

The First Successful Amputation at the Hip-joint in America.—Dr. A. H. Hubbard, of Fuerte, Mexico, writes: "I see in your issue of May 9th recorded the death of Dr. John Frederick May, stating that he was the first American surgeon that ever made a successful amputation at the hip-joint. I believe I am correct in saying that Dr. John Sweat, of Parsonsfield, Me., made the first successful amputation at the hip-joint in the town of Conway, N. H., about the year 1845. If I am not correct, I stand committed."

Alaska Indians Suffering from the Influenza.—Advices from Cook's Inlet, Alaska, say that large numbers of Indians near that place are dying from the grip. Within the week ending on May 19th twenty Indians died within a radius of five miles. In a village a few miles distant from the cutting, packing, and canning factory every one had died except two children.

Dr. Philip Platt Kissam, of Jamaica, L. I., died at his home in that village on the morning of June 12th, aged eighty years.

Has been on trial among physicians for very many years as a healing agent. **By far the Best Tar Soap made.**

NTON, 115 Fulton Street, New York.
lotan enclosing card. Please mention MEDICAL RECORD

EDICAL PRACTITIONERS.

Journalistic Change.—It is difficult to follow the rapid and bewildering changes in Philadelphia journalism. The latest announcement is that Dr. H. A. Hare has resigned the editorship of the *Medical News* and that Dr. George M. Gould has succeeded to his place. Dr. Gould has achieved and deserved a distinct reputation for his literary skill. We trust that he will favor his readers with editorial columns which will nullify the criticisms of his predecessor.

Resignation of Professor H. W. Williams.—Dr. Henry W. Williams has resigned the professorship of Ophthalmology in the Harvard Medical School, which he has held since 1871.

The Medical Department of Columbia College.—It is announced that a new committee of the trustees, consisting of Mr. Vanderbilt, Dr. Wheelock, Mr. Mitchell, Dr. Draper, and Mr. Potter, has been appointed on the College of Physicians and Surgeons; that the alumni association of the medical school has founded three fellowships of $500 each for two years; and that Dr. John G. Curtis, the professor of physiology, has given his physiological apparatus to the school.

Political Doctors in Austria.—Among the three hundred and fifty-three members of the Austrian House of Deputies there are ten members of the medical profession. The Austrian House of Lords numbers two hundred and fourteen members, among whom Professor Billroth, Brücke, and Schneider represent the medical profession.

The German Anatomical Society held its fifth general meeting at Munich on May 17th to 19th, under the presidency of Professor v. Kölliker. From seventy to eighty members were present, among whom were Professors Bardeleben (Jena), Bonnet, Braune, Flemming, Froriep, Henke, His, Gerlach, Kollmann, Merkel, Nussbaum, Oellacher, Rabl, Retzius (Stockholm), Schwalbe, Stieda, Strahl, Toldt, Tomiti (Pisa), Waldeyer, and many others. Many foreigners were present, Belgium, Holland, and Italy being particularly well represented. Professor v. Kölliker, in his presidential address, stated that the Society now numbered two hundred and fifty members, and included not only German anatomists but many foreign celebrities. He reiterated an opinion, which he said he had expressed before, that much confusion and loss of time would be saved if scientific papers were written only in German, English, French, or Italian. Good work was done by the Nomenclature Commitee, and the scientific programme included some important papers.

Dr. Ambrose Pratt died at his home in Chester, Conn., on June 18th. He was a graduate of Yale College, in 1837, and served as surgeon in the Twenty-second Connecticut Regiment during the war.

Publication of a Hindoo Medical Work.—The *Indian Medical Gazette* reports the publication of an ancient and long-lost treatise on Hindoo Medicine by Banga Sen, who is extensively quoted in all standard works on Hindoo medicine. The editor, a distinguished native physician of Shar Beri, in the remote district of Rohtak, in the Punjab, says that he could not procure a complete manuscript anywhere, but had to work on odd chapters from different families of Vaidyas in India.

Annual Variations in the Pulse-Rate.—Some one has had the curiosity and patience to keep a daily record of his pulse for a number of years, and reports that it has two cycles of increase and decrease in rapidity each year. It falls gradually and slightly through the spring until about midsummer, and then rises through the autumn to November or December. Then comes a second fall and a second rise, culminating in February.

Cremation in Liverpool.—The growing acceptance of the idea of cremation in Liverpool is evidenced by the fact that a company is arranging to construct a large crematorium in that city. It is said that the existing facilities for cremation are no longer adequate to the demand.

Ice-Cream Poisoning.—Many cases of ice-cream poisoning have been reported recently in Bloomington, Ill. In one case nearly one hundred children and others were poisoned by ice-cream eaten at a church festival, and several of them had narrow escapes from death. A similar result followed the eating of ice-cream at a wedding reception and banquet, and guests at other recent social gatherings have also been made more or less ill by the same cause.

A Woman's Hospital in Bosnia.—The Austrian Government proposes to erect shortly a hospital for women at Sarajevo in the Bosnian territory, and will give it in charge of female physicians. It has advertised that an examination will be held in the coming autumn or winter for applicants to several salaried positions in the staff of the hospital, the compensation being about $50 per month. This is a new name for the Austrian authorities, who have always resolutely done what they could to discourage women from studying medicine. They are forced to it, however, in their desire to conciliate the Bosnians in this comparatively newly acquired province. A woman's hospital is regarded as a powerful auxiliary in this pacification, but it is necessary to put female physicians in charge, as the women in Bosnia will have nothing to do with male doctors.

The Bacteriological World is the title of a monthly illustrated magazine for the study of microbes and diseases of bacterial and parasitic origin, edited by Dr. Paul Paquin, of Columbia, Mo.

Dr. Walter Wyman has been appointed Surgeon-General of the Marine Hospital Service, *vice* Dr. John B. Hamilton, resigned, to accept the position of Professor of Surgery in Rush Medical College, Chicago.

Colleges or Hospitals.—That was a very bright thing Mr. Depew said in his Cincinnati address. "Giving money for colleges," he said, "was better than giving it for hospitals. To give for hospitals was to give for repairs, to give for colleges was to give for construction and equipment." That was easy enough to say when once thought of, but the thinking of it was not so easy.—*Indianapolis Journal.*

Dr. Thomas P. Gary, of Jacksonville, Fla., President of the Florida Medical Association, at one time Mayor of Ocala, and one of her leading and most public-spirited citizens, died on June 10th. Dr. Gary was fifty-five years of age. He ranked high in the medical profession of the State, and his death will be universally regretted throughout Florida.

Dr. Gervis French, of Bainbridge, Chenango County, N. Y., died on June 10th. Dr. French was born in Springfield, Otsego County, N. Y., August 24, 1816, and for many years was a successful physician in this city, afterward retiring and engaging in the manufacture of drugs and medical supplies.

Dr. Grace Danforth, of Dallas, said, in an address to the Texas Medical Society, she had had a predilection for the medical profession since her *boyhood*. The fair physician seems to be a professional descendant of the Hibernian physician, who said that one of his patients came from a family in which it was hereditary not to have any children.—*Medical Standard.*

A Bogus Medical College in Chicago.—The National University of Chicago, chartered in 1889, recently granted a diploma dated 1884 to an Idaho man after about a month's study, according to Dr. T. D. Ross, of Shoshone.—*Medical Standard.*

The Lines Disappearing.— Dr. T. S. Armstrong, Superintendent of the Binghamton State Hospital for the Insane, and a homœopathist of liberal views, has been elected a member of the Binghamton Academy of Medicine, a local society of regular medical practitioners. The leading firm in this country of "homœopathic" chemists have issued prescription blanks without the sectarian designation.

Reviews and Notices of Books.

A Practical Manual of Gynecology. By G. R. Southwick, M.D., Assistant Professor of Obstetrics in the Boston School of Medicine, etc. Pp. xix., 532. Boston: Otis Clapp & Son. 1891.

This work, by a homœopathic *confrère*, is one of considerable merit, being evidently written by a practical gynecologist. We are compelled to take exception to a few of the author's statements. It is to be hoped that elaborate descriptions of the manner of using the uterine sound, especially for the purpose of replacing the uterus, will eventually be banished from manuals of gynecology. It is a dangerous instrument, even for an expert, and the *tour de maître* still taught by some authors is a relic of barbarism. Chapter II., on Minor Surgical Gynecology, is excellent; Chapters III. and IV., on Diseases of the Urethra and Bladder (an unusual situation for them) are weak. The chapter on Perineorrhaphy is fair, although the description of Emmet's operation for rectocele, with the accompanying illustrations, is not so clear as it might be. A valuable chapter on Puberty and the Climacteric has a formidable therapeutical appendage. We can imagine the practical surgeon laughing in his sleeve as he conscientiously fills out the lists of infallibles recommended by the authorities of his school. Amenorrhœa ought to yield to some of the numerous remedies. We read that "the therapeutics of the old school are rather limited, so far as any reliable internal medicines are concerned for uterine hemorrhage." This is true, but it is not such a great misfortune, after all. Dysmenorrhœa is divided into several varieties, according to the old theory, each having its bewildering number of specifics. The chapters on Displacements is fair, except the section on anteflexion, which is ancient history; the same is true of the chapters on Pelvic Inflammation and Diseases of the Ovaries. One of the most commendable features of the book is a concluding chapter on Massage of the Pelvic Organs (well illustrated), and another on Electricity—subjects much neglected by most writers. In general, we can commend this work as a useful working manual, suitable for the general (homœopathic) practitioner. Its value is enhanced by copious foot-notes, lists of authors, monographs, etc.

Diabetes: Its Causes, Symptoms, and Treatment. By Charles W. Purdy, M.D. Queen's University; Honorary Fellow of the Royal College of Physicians and Surgeons, Kingston; Member of the College of Physicians and Surgeons, Ontario; Member of the Association of American Physicians, of the American Medical Association, of the Chicago Academy of Sciences, etc. With Clinical Illustrations. Pp. 184. Philadelphia and London: F. A. Davis.

The author's long experience teaches that diet is the chief source of help in diabetes, and that disregard of the details of dieting constitutes the most frequent cause of failure in controlling the disease. Consequently he enters minutely into the matter, and illustrates his position by many clinical cases. The book is of especial value to Americans, as it brings out prominently the leading features of the disease as it occurs in the United States. His logical deduction is that the climate and waters of parts of America are as well suited to the treatment of diabetes as those of any other country on the globe.

Transactions of the American Association of Obstetricians and Gynecologists. Vol. III. Pp. xlv., 383. Philadelphia: W. J. Dornan & Co. 1890.

The present volume is fully up to the standard of its predecessors, and presents a most attractive appearance, containing as it does no less than four plates and forty-six wood-cuts. The papers are mostly short and to the point. Among the most notable are those by Hoffman, Price, Reed, Kellogg, and Bernardy. Short papers are contributed by Winckel, Freund, and Saenger. Some of the discussions are quite interesting, though occasionally the speakers are inclined to be rather dogmatic. A vein of personality, such as runs through the proceedings of the Philadelphia Obstetrical Society, is sometimes noted. The arrangements of the papers leaves much to be desired, as they are jumbled together without much regard for sequence.

Diseases of the Digestive Organs in Infancy and Childhood, with Chapters on the Investigation of Disease, the Diet, and General Management of Children, and Massage in Pædiatrics. By Louis Starr, M.D., Late Clinical Professor of Diseases of Children in the Hospital of the University of Pennsylvania; Physician to the Children's Hospital, Philadelphia; Consulting Pædiatrist to the Maternity Hospital, Philadelphia, etc. Second edition. Illustrated. Pp. xi., 396. Philadelphia: P. Blakiston, Son & Co.

Dr. Starr's excellent manual needs no introduction. The first edition was issued in 1886 and became immediately popular. The new edition is an improvement on the old, inasmuch as there are added chapters on alterations in the odor of the breath in disease, urine alterations, and massage in pædiatrics. Another important addition is a detailed account of second dentition and its influence on the health in late childhood, a subject which, the author truthfully remarks, has been greatly neglected. The author has brought his work abreast of the times.

The Modern Antipyretics, Their Action in Health and Disease. By Isaac Ott, M.D., Ex-Fellow in Biology, Johns Hopkins University; Ex-President of American Neurological Association; Consulting Physician to the Easton Hospital, etc. Illustrated. Pp. 52. Easton, Pa.: E. D. Vogel.

Dr. Ott's work is a thorough, careful study of fever and the modern means of controlling it. His experiments on the cause of pyrexia are original, and his deductions worthy of careful study. The antipyretics considered are the coal-tar products, most notable of which are antipyrine, antifebrin, phenacetin, and exalgin. His *résumé* of the properties of these drugs fills a want that has not before been fully supplied.

A Contribution to the Natural History of Scarlatina, Derived from Observations of the London Epidemic of 1887–88. By D. Astley Gresswell, M.A., M.D. Oxon. Pp. 205. Oxford: Clarendon Press.

The value of this work is vouched for by the faculty of the University of Oxford. It was the author's dissertation for the degree of Doctor of Medicine, and was printed and published at the expense of the University as a mark of distinction on account of its exceptional excellence. A more complete, careful, scientific study of scarlatina does not exist in medicine, and the book has received unbounded praise from all sides. The cases studied numbered 588, embracing all ages and taking into account all seasons of the year. Each prominent symptom, especially albuminuria and pulse-rate, is studied in detail; chapters are devoted to the influences of age, sex, surroundings, seasons, etc., on the disease, and all in all the work is a masterly and exceedingly valuable one.

Aphorisms in Applied Anatomy and Operative Surgery. By Thomas Cooke, B.A., B.Sc., M.D. Paris; F.R.C.S. England; Senior Assistant Surgeon to the Westminster Hospital, and Lecturer at the School of Anatomy, Physiology, and Surgery. London and New York: Longmans, Green & Co.

This is a book for the student's use in his final examinations, and to help him fix the prominent and important parts of anatomy and surgery in his mind. The book includes 100 typical *viva voce* questions in surface-markings, and a great mass of useful material tersely stated.

Society Reports.

NEW YORK STATE MEDICAL ASSOCIATION. FIFTH DISTRICT BRANCH.

Seventh Annual Meeting, held in Brooklyn, May 26, 1891.

STEPHEN SMITH, M.D., PRESIDENT, IN THE CHAIR.

MORNING SESSION.

AFTER a few introductory remarks by the President, the regular business of the Branch was transacted, including the appointment of a Nominating Committee to nominate members of the Executive Committee for the ensuing year. The Secretary, DR. E. H. SQUIBB, then read the following biographical sketches of deceased Fellows: Dr. James Bathgate, by Dr. John Shrady; Dr. W. N. Blakeman, by A. N. Blakeman, Esq.; Dr. John P. Garrish, by Dr. William T. White.

The Treatment of Hydrocele by Carbolic Injection Versus the Radical Operation.—DR. SAMUEL E. MILLIKEN read a paper on this subject. The radical or cutting operation of Volkmann, and its various modifications, he said, while usually successful in relieving the hydrocele, required the use of an anæsthetic and a week or more in bed should suppuration occur. The method of Levis, by carbolic injection, was practically painless, confinement to bed was in no sense essential, and unless an inordinate amount of carbolic acid (over thirty minims) were used, sloughing ought never to occur. The simplest and most efficient apparatus for the purpose was a small trocar and a hypodermic syringe. After thorough evacuation the syringe was screwed on to the cannula, and the injection could thus be made without a single drop of the acid coming in contact with the skin of the scrotum. When from five to twenty-five minims of pure carbolic acid was distributed over the whole serous surface (two or three minims in each place) nothing more than a sense of warmth was experienced by the patient. After removal of the cannula slight kneading of the sac might be made to insure thorough coating of its walls with the irritant. Usually within twenty-four hours the height of the inflammatory reaction would have been reached; and thus, if a laboring man were injected on Saturday, he would be entirely able to go to his work as usual on Monday morning.

Of 54 cases thus treated by Dr. Milliken at the Hospital for Ruptured and Crippled 9 were never seen after the injection, 5 paid one visit within the first week only, and 4 were at present under observation. All the remaining 36 could be set down as completely cured; and of these 27 had one injection, 4 had two injections, and 5 had three injections. In no case had sloughing occurred, and not one of the patients lost more than twenty-four hours from business. From two to six weeks was necessary for absorption of the exudation to take place, and thickening of the sac might remain much longer than this.

The conclusions reached by the author were as follows: 1. Carbolic injection is a safe method for the cure of hydrocele. 2. It is practically painless. 3. The patient can attend to business without more than one day's delay. 4. The disagreeable effects of an anæsthetic are avoided.

DR. WILLIAM R. BALLOU thought that the injection of carbolic acid was greatly preferable to that of iodine. Hare had collected a large number of cases in which great destruction of the tissues, and one case in which fatal iodine-poisoning, was caused by the latter. The danger of iodine-poisoning seemed to him to be the most serious objection to the use of this agent. He should like to call attention to one point, and that was, that thin sacs do not require carbolic injection. At the New York Polyclinic Dr. Fluhrer used an aspiratory needle three inches long and of rather large calibre in connection with the hypodermic syringe. A solid metal staff having been introduced into the urethra, the fluid was evacuated and a large quantity of carbolic acid (from sixty to eighty minims) was injected into the sac. It seemed to him, however, unnecessary to use such a large amount when such excellent results as those reported by Dr. Milliken could be obtained with a small amount. In cases of Bright's disease the method by carbolic injection was especially indicated, since the Volkmann operation required the use of an anæsthetic, and it was well known how dangerous ether was when disease of the kidneys was present.

DR. WILLIAM T. WHITE said that he had never used carbolic injection, but had always depended on the use of iodine, from which he had never seen any of the bad results that had been spoken of. The first injection was almost always successful; so that it was seldom necessary to repeat it. Sometimes, however, considerable inflammation was occasioned, necessitating the patient's remaining in bed for two or three days, and if this could be avoided by the use of carbolic acid it was certainly a point gained.

DR. MILLIKEN said that he had omitted in the paper to say that he usually directed a suspensory bandage to be worn for the first two weeks, and that he employed for the injection equal parts of glycerine and carbolic acid. It was important that there should always be sufficient fluid to make a perfect solution. He preferred to use ten to twenty minims, and repeat the injection a second, or even a third time, if necessary, rather than to use a large quantity of the acid a single time. In cases where the trouble returned it was always noticeable that the hydrocele was never as large as it had been originally. He had never had any personal experience with the use of iodine, but in all the cases that he had seen treated in this way by others the pain inflicted was much greater than when carbolic acid was employed. In regard to iodine, he was not so much in fear of the sloughing liable to be caused by it as of iodine poisoning. The painlessness of carbolic acid he thought was a great point in its favor. With it, it was never necessary to use cocaine, as the puncture of the small trocar did not cause any more inconvenience than that of the hypodermic needle for the introduction of cocaine.

DR. JOHN MURPHY said that he had known of three or four cases in which carbolic acid used in this way was followed by very bad effects, especially on the kidneys. About a year ago he had seen a case of this kind terminate fatally, and he could not attribute the death to anything but carbolic-poisoning. It was very difficult to eliminate carbolic acid from the system, and it was very apt to have some destructive action and to select the kidneys for this. In his opinion there was nothing better for the treatment of hydrocele by injection than Lugol's solution, and he had never seen any bad effects result from its use.

In reply to questions by the Chair and others, Dr. Murphy stated that he did not know the quantity of carbolic acid that was used in the fatal case he had mentioned, and that death occurred some three weeks after the carbolic injection. Considerable doubt as to the correctness of Dr. Murphy's view that death was due to poisoning by carbolic acid in this case was expressed by a number of those present.

Acute Prostatitis and Prostatic Abscess was the subject of a paper by DR. WILLIAM R. BALLOU. In one thousand cases of urethritis, in various stages, seen in hospital and dispensary practice during the past five years, he said he had observed only three cases of prostatitis resulting in an abscess of the gland, though many that were of a milder grade. In the mildest form of the affection there was little or no swelling of the gland or adjacent parts. In the more severe form the termination might be either in resolution or in prostatic abscess. Many distinct foci of suppuration were sometimes present, and perforation and discharge might be either into the urethra, the rectum, or the perinæum. In case of discharge

into the rectum the infiltration of the surrounding connective tissue was very marked, and was occasionally so extensive as to eventuate in periprostatic abscess.

The most frequent cause was extension of inflammation from the anterior urethra; and among the other causes were cold, traumatism (including the use of instruments), and irritating urethral injections. Having described the symptoms in the milder form, he said that in the severer form the temperature might rise to 104½° F., as in one of the cases detailed later on. Swelling, pain, and throbbing in the rectum were marked, and defecation might be painful or much interfered with. In another of his cases the fæces were compressed to tape-like worms in consequence of the swelling. As the formation of pus came on, all the symptoms became intensified, and even general movements of the body were accompanied by agonizing pain. The temperature rose suddenly, and was usually accompanied by rigors and sweating. More or less complete retention of urine might also be present; but prostatic fistula or extravasation of urine was rare, owing to the fact that the surrounding tissues were very tense from cellular infiltration.

After a few remarks on prognosis, he passed on to the treatment, and said that in the beginning all local urethral medication was to be stopped, and absolute rest in bed enforced whenever this was practicable. A brisk purge was advisable, at first, and later on laxatives were to be given at intervals. Such alkalies as citrate of potassium (10 grains), or liquor potassæ (5 drops), given every three hours with two drachm doses of tincture of hyoscyamus he had found most efficacious in diminishing the pain and frequency of micturition, and he advised that they should be kept up during the whole course of the disease. Local remedies to the perinæum, such as leeches, hot fomentations, fly-blisters, and cantharidal collodion, as well as hot hip-baths, were often of service. Morphia internally, or suppositories of opium and belladonna were sometimes required by the intense pain present. If retention of urine occurred, a soft catheter should be passed after irrigating the urethra with a mild solution of permanganate of potassium. Incidentally Dr. Ballou spoke of the usefulness of this agent in ordinary urethritis. After drawing off the water, the bladder should also be washed out. In some cases of retention a metallic instrument might be required, but it should be used with great caution, as the softened prostate might be easily lacerated and false routes found. Aspiration above the pubes might be sometimes preferable.

If abscess formed, a free incision was to be made; the cut varying in position in different cases according to the tendency to pointing. Even if fluctuation were not distinct, a free and deep perineal or rectal incision should be made in case abscess was suspected. After evacuation, under antiseptic precautions, the abscess should be washed out with bichloride solution (1 to 3,000), and a large drainage-tube inserted. Passage of a sound into the bladder, in the hope of rupturing the abscess into the urethra, had been sometimes recommended. In conclusion, Dr. Ballou gave the notes of three cases of acute prostatic abscess treated by him. In one, the abscess had discharged spontaneously into the rectum before the patient came under observation; in another it was tapped with a trocar through the rectum; and in the third, an incision was made from the rectum (after the introduction of a Sims metal speculum) with a long, narrow blade.

The President said that in the earlier stages he thought it preferable to make the perineal rather than the rectal incision, on account of the danger, with the latter, of the opening remaining permanently, and also of infiltration of the tissues. If the case were seen later, and the abscess was evidently pointing toward the rectum, he would perform rectal incision. He regarded the passage of a metallic instrument into the bladder, with the idea of causing rupture into the urethra, as a dangerous and unjustifiable procedure, and referred to a case where this was done which terminated fatally in consequence.

Dr. Ballou said objection to rectal incision had been often urged, on the ground that it was liable to result in fistula and extravasation; but according to one of the latest and best authorities, Moullin, such a result was not nearly so common as had been heretofore believed.

The Treatment of Gonorrhœa.—In reply to a question by one of the Fellows, Dr. Ballou stated that he was in the habit of using in acute urethritis bi-hourly injections of the strength of one-eighth to one-tenth of a grain of permanganate of potassium to the ounce of distilled water, two syringefuls being employed at each injection. Internally he usually gave some alkali, and if the trouble were deep-seated, hyoscyamus in addition. After from four to eight days sulphate or acetate of zinc (one grain to the ounce) was added to the injection. This treatment had proved very efficient in his hands, and was, he thought, shorter than other methods.

Dr. William McCollom said that it might be objected to such a weak permanganate solution as that used by Dr. Ballou that it was scarcely germicidal. He himself had generally used the permanganate in the strength of one grain, or, at all events, half a grain, to the ounce.

Dr. Ballou thought that the gonococcus at the present time was not regarded as of quite as much importance as formerly. It was only in the first stage of urethritis that he used the permanganate in as weak a solution as one-eighth or one-tenth of a grain to the ounce. Afterward he often increased the strength to one-sixth of a grain, and this was as strong as he ever employed it.

Dr. Pritchard said that he had formerly used permanganate of potassium, but had now given it up. With this injection, as with most others, the discharge disappeared for a time, but it almost always returned.

Afternoon Session.

Opiates in the Treatment of Acute Peritonitis.—The President delivered an address on this subject (see p. 613).

Dr. A. Palmer Dudley had been announced to read a paper on "Cathartics in the Treatment of Acute Peritonitis," which was to follow the President's address, but he failed to appear.

Dr. Alfred L. Carroll said that although, happily, puerperal peritonitis had now become a comparatively rare affection, peritonitis from other causes was still met with sufficiently often to make its treatment of very great practical interest to the profession. It was noticeable that the advocacy of saline cathartics in this connection came, as a rule, from the abdominal surgeons. For instance, Lawson Tait was the chief defender of their use. If, after an operation, peritonitis occurred, he gave turpentine and seidlitz powder, and he considered this mode of treatment better than any other. It seemed to him (Dr. Carroll), however, that there was a great difference between such cases as these and the septic peritonitis, which is hard to deal with in puerperal form. The enormous distention of the abdomen, he thought, indicated an effort to get rid of something; and here good results had been obtained by the moderate use of purgatives. In puerperal peritonitis, which was at first visceral, and afterward extended to the parietes, opium was, in his opinion, strongly indicated. This quieted reflex irritation, and prevented the rubbing upon each other of the inflamed surfaces. In such cases he would give an occasional mild cathartic in connection with the opium.

Dr. J. W. S. Gouley said that he was able to add two cases of recovery from puerperal peritonitis under Dr. Clark's treatment to those which had been given in the paper. They occurred at Bellevue Hospital, in the year 1853, when he was an *interne* there; and the opium was pushed to such an extent in these cases that the respirations were kept down to between six and nine a minute. He then said that he should like to ask the President what the action of such free administration of opium was upon the capillary circulation. This

might, perhaps, explain the success of the opium treatment.

Dr. Thomas H. Manley referred to the discussion on the management of peritonitis by active surgical interference in the surgical section of the American Medical Association at the Newport meeting, and spoke of the extreme opposition with which everything in the way of palliative treatment was met. Peritonitis, he said, was regarded as seldom or never idiopathic, but always due to some special cause. In the medical treatment mercury was strongly advocated by some, particularly among the older practitioners, and opium was also recommended as an important adjuvant. His own experience had led him to regard the opening of the peritoneal cavity as always a serious matter, and not the mere bagatelle that many seemed to consider it. In the next ten years he believed that there would be fewer laparotomies performed for the relief of inflammatory conditions than during the past ten years.

In the cases reported in the paper, opium was given in an entirely empirical way. In every case of such peritonitis we had paresis of the bowels in the beginning of the attack, and, as a rule, they did not act upon the paretic condition of the intestinal walls. It was also an incontestable fact that opium had a distinct and specific action here. In induced peritonitis (the result of surgical operations, septic infection, etc.), we had this paretic state, with shock following. As regards the benefit from opium, all had seen its wonderful power in moderating peritonitis. Still, a drawback to its use was found in the idiosyncrasies of certain patients. He had seen fatal results produced in one case (a female of nineteen) by the administration per rectum of half a grain of the extract of opium.

Dr. William McCollom said that the paper recalled to him very vividly his first impressions in regard to the treatment of peritonitis. He was then at Woodstock, Vermont, where Professor Clark used to lecture at the Medical School, and he saw with his preceptors a good many cases of acute peritonitis which were not of puerperal or septic origin, but belonged to the variety known as idiopathic, and were due to the same influences which produced acute pleurisy, for instance, such as cold, exposure, etc. The physicians used to commence the treatment by bleeding, and then they gave cathartics. As Dr. Manley had stated, there was a paresis of the intestinal walls at the outset of this affection, and they had an idea that peritonitis commenced with some obstruction of the bowels. They began with calomel and jalap, and if this medication failed, resorted to castor-oil. The result was that the patient was agonized with pain, and in a day or two died.

Soon after he himself began to practise he heard of Dr. Clark's opium treatment of peritonitis, and he resolved to try it at the earliest opportunity that presented itself. The first case that he met with was that of a young girl, and he gave her as much as fifty grains in one day, remaining himself in close attendance, and watching the effects of the drug. The good result in this case induced him to pursue the same treatment in others, and he found that he saved almost all of his peritonitis cases. He gave enough opium to reduce the respirations to 8 or 9 per minute, and not only was life saved, but all pain was abolished and vomiting and other disagreeable symptoms checked. He had now carried out this practice for thirty-eight years, and he firmly believed that the opium treatment was the best of all in peritonitis.

Dr. Murray said that while he also considered opium the best remedy in peritonitis, he thought it necessary to take into consideration the special character and antecedent history of each case. For instance, in a patient such as one he now called to mind, who had at one time contracted the morphia habit in consequence of having used the drug freely for the relief of violent hemicrania, he had some doubt whether it would be justifiable to give opium in case he should be attacked with peritonitis.

The President, in closing the discussion, said that he did not wish to be misunderstood as regards the paper he had read. Its object was merely to set forth the history of the introduction of the treatment of peritonitis by opium into Bellevue Hospital, and not to advocate the claims of this plan of treatment in general. He regretted very much that Dr. Dudley had been prevented from being present and reading his paper on the use of cathartics in peritonitis.

Dr. Gouley moved, in view of the great interest attaching to this subject, that the Committee of Arrangements for the next annual meeting of the New York State Medical Association should be requested to make provision at the meeting for a discussion on the "Treatment of Peritonitis," to be opened by the President, Dr. Stephen Smith. This was unanimously carried.

Practical Results of the Operation for Lacerated Cervix Uteri.—Dr. H. W. Mitchell read the paper. The operation of trachelorrhaphy, he said, aimed primarily to restore the contour of the cervix uteri to its normal condition. A higher and vastly more important aim was to insure its future usefulness. A patient who had undergone this operation should be so far restored to her original and normal condition as to enable her to assume future pregnancies and to pass through parturition safely, successfully, and without a repetition of the former lesion. With proper attention to details in performing the operation and in the subsequent care of the patient, healing by primary union was the almost invariable result. In a record of two hundred cases Dr. Mitchell said that only two healed by granulation, the others all healed by primary union.

Of these 200 cases, he had been able to follow up 21 cases where subsequent confinements had taken place; and of these 21 cases 8 had had more than one subsequent confinement. These 21 cases had been attended personally by himself at the time of confinement, and he proceeded to give a *résumé* of them. All were of a severe form of laceration, and in seven there was laceration of the perineum in addition. Re laceration of the cervix during subsequent confinements occurred in only two of the cases, and in both instances it was so very slight as not to impair the usefulness of the cervix or render a second operation necessary. In conclusion, he said that if he might judge by these 21 cases (which were all that he had the opportunity to observe in which he was familiar with all the details), he could say with truth that the operation was a proper and successful one, and accomplished the following results: 1. To diminish the pain and irritation following upon such a distressing lesion. 2. To relieve the sense of bearing down. 3. To cure the exhausting leucorrhœal discharge, to restore the parts to their normal and healthful condition, and, above all, to restore the natural features of the cervix so that future pregnancies and labors may take place in a natural and healthy manner, and without subjecting the patient again to the train of distressing and painful symptoms calling for the operation of trachelorrhaphy.

Objections to Ordinary Axis-traction Instruments; also the Advantages of the Anti-Craniotomy Forceps over Version in Pelvic Deformities.—Dr. T. J. McGillicuddy read a paper on this subject. While the correctness of the principle of axis traction, he said, was conceded by all, there were still many fallacious ideas in connection with its production. Three of the most common of these were: 1, That it is necessary to have rods attached to the blades by a movable joint; 2, that the traction, whether with tapes or rods, must in no way be connected with the handles, which must move freely in all directions; and 3, that rotation and flexion of the head can take place only when Tarnier's instrument, or one similar to it, is used. These ideas, he believed, were detrimental to proper axis-traction, as it was well known that in the skilful use of the forceps we should frequently unlock the blades that the head might undergo rotation and accommodate itself to the pelvic canal; and

it was also a fact that Tarnier's instrument, when clapped to the infant's head, interferes with rotation. Pajot, Herbst Novales, and Albert H. Smith all recognized that axis-traction could be made without any such complicated attachments to the ordinary forceps.

With the instrument (described in the *American Journal of Obstetrics* for December, 1889) which he had devised Dr. McGillicuddy said we could make ideal axis-traction during the entire passage of the fœtal head with remarkable ease and safety. While in relation to Tarnier's instrument a great deal had been said of the indicator, in this forceps the indicator was in the hands of the operator, pointing out the direction of traction as well as the resistance. With it rotation in the posterior positions could be readily made by means of the adjunct handles, if it was thought best to use the forceps for that purpose. It was easy of application, and in its dual character it had all the advantages of axis-traction and the ordinary forceps, and saved the expense of buying two instruments.

Passing on to the second part of the paper, he said that the forceps had an undoubted place as a compressor in certain cases. We were at all times to follow nature's guidance, and it was well known how frequently the infant's head became elongated and otherwise distorted by pressure in its passage through the pelvis, yet without damage to the cranial contents. The whole upper segment of the infantile brain (relatively its non-vital part) would stand considerable compression without danger, while the bi-mastoid or basal region was the vital portion, which nature had so wisely protected by making it uncompressible. The death of the infant was generally caused when the ordinary cephalotribe was used by the close approximation of its tips, thus fracturing this part and causing pressure on the medulla. Therefore, as some compression of the infant's head was compatible with its safety, and as there was no modern instrument, so far as he was aware, that stood between the ordinary forceps and the cephalotribe or cranioclast, he thought there could be no doubt of the utility of the instrument which he now presented, which was intended to be used as a substitute for craniotomy or version in cases of pelvic contraction of moderate degree, or where the common forceps was unsuccessful. It was an efficient tractor, and at the same time it made moderate transient compression of the flexible infantile cranium in its upper portion, while it did not press too strongly on the child's neck with its tips.

Thus it gave the child a chance for its life, while it minimized the risk to the mother. It was safer for the mother than craniotomy, and it was also quicker and better than turning. Transient compression by the forceps was no more dangerous than compression by the contracted pelvis in version, and traction by the forceps was much less dangerous than traction by the lower extremities, which frequently disjointed the neck, compressed the funis, and even decapitated.

Dr. McGillicuddy made a comparison of the advantages claimed for turning by Simpson and those of the anti-craniotomy forceps as follows :

In Favor of Turning.	*In Favor of the Anti-craniotomy Forceps.*
1. The fœtal head has the shape of a cone with the base upward, and when the trunk is delivered the smaller part of this cone may engage in the superior strait.	1. The fœtal head after moulding on appliation of the forceps has the shape of an olive, and either end may engage in the superior strait.
2. The solid hold given by the body of the fœtus when it is delivered first allows us to use force enough to cause compression of the head and to bring, if need be, the elastic and larger part of the cone into the greatest space in the contracted pelvis.	2. The anti-craniotomy forceps gives a much better hold and causes slight compression, if needed.
3. The head drawn through the contracted pelvis generally adapts itself or may be caused to adapt itself in such a manner as to bring its smallest diameter, the bi-temporal, instead of the bi-parietal, into the most contracted diameter of the pelvic strait.	3. The same thing occurs in cephalic presentation.
4. The cranial vault is more readily compressed when the force is applied to the lateral surfaces, as it is in the case of the aftercoming head.	4. With moulding and application of the forceps you compress not only the lateral surfaces but the fronto-occipital surfaces as well.

Simpson's Conclusions in Favor of Version.	*In Favor of the Anti-craniotomy Forceps.*
1. The duration and hence the danger of labor is diminished by version. Therefore version should be resorted to as soon as dilatation is complete, without waiting for engagement of the head.	1. It is not diminished as much as when this forceps is used. It can be applied, if necessary, before engagement of the head, as well as after.
2. Compression of the fœtal head is compatible with life.	2. If this is true, why not use the forceps?
3. The traction to which the fœtal neck is subjected is not incompatible with fœtal life.	3. The traction to which the fœtal neck is subjected often kills and sometimes decapitates it.
4. The risk of death from compression of the cord is not great enough to cause rejection of version.	4. There is no risk of death from compression of the cord in the use of the forceps.
5. Energetic but rapid compression is less dangerous to mother and to infant than less, but prolonged, compression.	5. It is the same with the forceps.
6. Local lesions of the vagina, fistulæ, etc., are more likely to result from forceps than from version.	6. Local lesions generally result from impaction with delay (version), and least of all from improper use of the forceps.
7. The risk of rupture of the uterus during version has been exaggerated.	7. There is much more risk of rupture with version than with the forceps.

This instrument, Dr. McGillicuddy said, was not a cephalotribe or cranioclast, but a conservative, life-saving forceps, to be used in cases of considerable pelvic deformity. No woman should be delivered except by axis-traction and with its axis-traction handles one could determine the exact amount of resistance and the proper amount of force to use, and readily use it. With this forceps we pulled directly in the axis of the brim. The conclusion at which he had aimed was, that when this instrument cannot deliver a living child there is no other operative alternative but Cæsarean section, as craniotomy in the living fœtus is not justifiable.

A Case of Obstinate Neuralgia Following Fracture Relieved by Operation, was the subject of a paper by Dr. Reginald H. Sayre. The patient was a young man, aged nineteen. When five years old he fell and fractured the right femur in its upper third. At the age of nine he refractured the right femur at a point a little higher than the former injury, and also dislocated the hip. When thirteen he fractured the right femur for the third time, and this time the bones (in which there had previously been straight union), united at an angle, causing a very morbid curving of the thigh and between two and three inches of shortening. After the last accident he had constant pain in the limb, which was greatly aggravated by motion or by handling of the parts and most intense at the point of greatest deformity, which was just in the line of the external cutaneous nerve. At last the pain increased so much that he had to resort to the continual use of morphia. The wearing of a high shoe and the use of blisters and strong galvanism proved entirely ineffectual, and the suffering grew steadily worse.

Several surgeons concurred in the opinion that there was a large exostosis pressing on the nerve, and on June 10, 1888, Dr. Sayre operated under antiseptic precautions. He found to his surprise that part of the vastus externus muscle was so twisted on itself as to turn at right angles to the long axis of the femur, but that there was no exostosis present, with the exception of a most minute point which could scarcely be considered abnormal, but which he nevertheless removed. He then passed his finger completely around the femur, stripping up the

muscles for an extent of two or more inches, but failed to find any sharp projection or anything else to account for the pain. Contrary to his expectations under these circumstances, he found that the patient was completely cured by the operation of the neuralgia pains, which he had then suffered for six years and which had resisted all kinds of treatment. On January 29, 1891, Dr. Sayre received a letter from the patient, in which he stated that he was still entirely free from pain.

One of the points of interest in this case was the simulation of an exostosis by what was presumably a tense fibre of the fascia lata which had become so much bound down as to press on the muscles of the thigh, and which by girdling them apparently caused the pain. He said he did not clearly understand how to account for the obliteration of pain. He did not consider the point of bone he removed large enough to have caused the trouble, and he did not think that when he passed his finger around the femur he tore loose any nerve-fibres from the cavity. The explanation, he suspected, was to be found in the relief of tension given by splitting up the fascia lata, which certainly bound the muscles very tightly. The length of time that had elapsed since the operation, nearly three years, he thought was sufficient guarantee that the cure would be permanent, especially as the patient had been addicted to the opium habit; and such *habitués* were proverbially hard to cure of neuralgias, since the latter offered so good an excuse for resuming their old habits.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, May 25, 1891.

ORLANDO B. DOUGLAS, M.D., PRESIDENT, IN THE CHAIR.

A Thrifty Society.—THE PRESIDENT said that at the last meeting the number of new members admitted was seventy-five; at this meeting it was thirty. The total number of members who now paid their dues regularly was over eleven hundred. We could take just pride in being the oldest and largest medical society in the United States.

Epileptic Insanity: Its Etiology, Course, and Treatment, Based on the Observation of One Hundred Cases.—DR. E. D. FISHER read the paper. He accepted the definition of epileptic insanity given by W. Bevan Lewis, as that form of mental derangement, the antecedent history, oncome, and further development of which showed an intimate connection with the epileptic neurosis. The distinction between epilepsy and epileptic insanity was often difficult, if not impossible, to make. We might consider epileptic insanity as a mental condition to which all epileptics were liable, and while mental impairment was often not recognizable in many cases during the intervals between the attacks, yet he was inclined to think from experience that it was more commonly present than had generally been stated. The great majority showed evidence of gradual deterioration.

The most important element in epilepsy was the disturbance of the consciousness, especially when sudden in its onset. This stood out as the real diagnostic symptom of the disease, and it indicated essentially an affection of the cortex of the brain, where, indeed, future study must be directed if we were to find its pathological basis. The convulsions were of secondary importance, since they might be due to various irritative lesions of the brain, causing the same character and distribution of convulsions as seen in epilepsy, and yet having none or little of the characteristic mental disturbance. In fact, in epilepsy of the so-called *petit mal* type, without convulsions, mental derangement was more common, and the prognosis was worse than in the *grand mal* type.

There was some similarity in all cases of insanity, especially in the change of the ego, or the relation of self to the external world. Then came a change in the emotions, then in the thought, as represented by illusions and delusions, and sooner or later dementia. It was desirable, however, in each case of epileptic insanity to study its own characteristic symptoms in addition to those which it had in common with all others.

Of his 100 cases, 60 were in women, 40 in men. There was a history of phthisis in the parents in 7 cases; in the male cases excessive use of liquor in 9; none in the female; shock in 6 women; insolation in 3 men; trauma in 6; a history of epilepsy from childhood in 12 women, 19 men, and an indefinite account of a fall in some cases.

With regard to the exciting cause, in sixteen women the menstrual period was the only time of the attack. A premonitory stage, shown by restlessness and irritability, was more common in women. A definite aura was rare. The character of the seizure was the same as in the general neurosis, except that it was rarely unilateral. Out of this hundred cases, and many others, the author had found few pointing to a focal lesion which would justify an operation.

The mental condition following and preceding the seizure, and the intermediate state, was what marked the disease. Masked epilepsy, in which mental derangement took the place of the epileptic seizure, was not present in any of the cases, although attacks of *petit mal* with excitement or depression were not uncommon. A tendency to violence following the attacks was present in 14 women, in 12 men; homicidal mania in 9 women, apparently in none of the men; melancholia with suicidal attempt in 13 women, comparatively few men. Delusions of persecution were not uncommon, especially in women. Hallucinations were rare. Fully fifty per cent. were demented.

Perhaps no class of patients presented such sudden and violent outbreaks as the epileptic insane. This showed the necessity for treatment in an institution. The disease showed a chronic course. The longest duration in his cases was forty-four years, the majority extending over ten or twenty years—most of them having been epileptic a number of years before coming to the hospital. They were the most troublesome of all inmates of asylums. They should be in an institution by themselves.

Various remedies had been used. His personal experience had convinced him that bromides were well borne when given sufficiently diluted, and that the tendency was to bear them better as the length of time of administration extended; in comparatively few cases did evil results follow their use.

Are Bromides Harmless?—DR. A. D. ROCKWELL said that in studying the mental phenomena connected with epilepsy, it was necessary to distinguish between those produced by the disease and those produced by medicines. He thought it must have been observed by all, that, however careful we may have been in the administration of bromides, yet we did meet with emotional impairment amounting sometimes to suicidal or homicidal tendency. He had for five or six years given in connection with the bromides a little chloral, say ten or fifteen grains of the former and two or three grains of chloral, and had found that thus administered more was accomplished than when the bromides were given alone, while the tendency to mental symptoms was diminished. He also thought the galvanic current had proven useful, not alone, but in connection with bromides.

DR. CHARLES HENRY BROWN thought there was one feature of epileptic insanity which stamped it at once as epileptic, namely, the suddenness of the onset and entire charge of personality, the entire forgetfulness of what had occurred through the seizure. In most other cases of insanity the patient remembered what occurred during his maniacal seizure. In the stage of dementia the differential point of loss of personality in epileptic insanity was less easily determined. As a rule, the insanity,

as soon as it made its appearance, was chronic, which pointed to the necessity for a well-regulated asylum, and he thought there was good prospect of the legislature of this State passing a bill providing for one. As to medicines, bromides held the first place; chloral and also counter-irritation were good emergency remedies.

Dr. Ralph L. Parsons said it sometimes became a medico-legal question whether a homicide had epileptic insanity, especially when there was no distinct history of well-marked epileptic seizures. A point in favor of such a diagnosis was want of real motive in the homicidal attack. The tendency of epilepsy was toward feebleness of memory and intellect, and toward degradation. He had never seen a favorable case which had already become insane. As to treatment, he had in a few cases used a heroic remedy with success, namely, strychnia, to the extent of producing its physiological effect, long continued.

Dr. John Messenger had found cimicifuga the most reliable remedy.

Applies a Ligature.—Dr J. Leonard Corning thought the best thing to do with patients during the paroxysm was to put them into a padded cell. Like pneumonia, the attack had a course to run before it could be stopped. To avoid the acne and unfavorable results of large doses of bromides, he had found ligatures placed around the extremities most useful. All medicines which had an affinity for the brain and spinal cord showed much greater potency when aided by this mechanical device. The method was much more practical than pressure on the carotids, which he had once practised. The ligature or ligatures need not be worn all the time, although they might be if thought desirable. He had also used chloral and other remedies.

Let Alone Plan.—Dr. W. M. Leszynsky had had considerable experience with insane epileptics in asylums, and had found they were a hopeless set of cases. In the status epilepticus they died, which was the best thing that could happen to them. Nothing would cure them. Bromides and other remedies might control the attacks, but they had to be given in such doses as not only disturbed the digestion but also kept the patient in a condition of mental enfeeblement. It seemed to him the best thing to do with chronic epileptics was to do very little except incarcerate them.

Dr. Fisher closed the discussion, and said that Dr. Leszynsky's plan was not very encouraging to the patient nor satisfactory to the physician.

Improvements and Adaptation of the Edison Current to General Office Use.—Dr. H. G. Piffard read a paper and made an elaborate demonstration of this subject, which at the conclusion elicited a vote of thanks from the Society. An experience of more than a year with the street current had satisfied him of its adaptability to office use. Since he had read a paper on the subject, over a year ago, he had made certain improvements in the method of applying the street current (the Edison only), so that now one could obtain the continuous galvanic current, the slowly or rapidly fluctuating current, the primary and secondary faradic currents, could charge a storage battery, or run saws, knives, and cautery by motor, and generate ozone. He had made provision for six independent circuits, in some instances two of which could be in simultaneous operation. The mechanism, independent of the motor, made the current perfectly safe, since the passage of over five hundred milliampères would destroy the carbon filament and break the circuit. The author not only described and demonstrated the outfit presented, but also explained certain terms used by electricians, as volt, ohm, milliampère, how to convert algebraically electrical energy represented by these terms into Watts's horse power, etc. He did not neglect to criticise some articles in the medical journals which showed some degree of ignorance of the principles of electricity. He made use of a modified Bailey rheostat, a Weston meter (said the McIntosh was also a good one), of a one-eighth horse-power C. & C. electro-motor. The Ford Instrument Company had agreed to make the whole out fit without modifying it, which he thought would insure its reliability.

The usual collation was served.

NEW YORK ACADEMY OF MEDICINE.

SECTION ON OBSTETRICS AND GYNECOLOGY.

Stated Meeting, April 23, 1891.

Egbert H. Grandin, M.D., Chairman.

The Secretaryship.—Dr. I. H. Hance sent a letter offering his resignation as secretary, as he was to be absent from the city for a year. The resignation was accepted with regret, and Dr. J. C. Edgar was elected to act for the remainder of the term.

Auvard's Incubator.—Dr. J. C. Edgar exhibited and described Auvard's couvert, made in Paris, there being, as far as he knew, only two of the kind in the city. It was not a new device, but for some reason had not been introduced into this country. Its advantages over the Tarnier and others were simplicity, ease of management, and cheapness. It cost in Paris about sixteen dollars, here, with duties added, about twenty-seven dollars. It consisted of a box with an upper and lower compartment, the babe lying in the upper, the lower containing bottles of hot water which were renewed from time to time, the temperature of the air being indicated by a thermometer visible from the glass top. Air entered a window below, passed over the bottles, over the thermometer, then reached the living compartment, and passed out at an opening above. It received moisture from dampened sponges.

The Chairman believed this incubator had the reputation, in Paris, of saving twenty-five per cent. more infants than any other, and he hoped some instrument-maker in this country would devise an equally good, simple, and cheap one, since the one exhibited was patented.

Nephrectomy.—Dr. Malcolm McLean related a case in which he had recently performed nephrectomy, the kidney tissue having, it seemed, entirely disappeared, to give place to a cystic tumor weighing twenty-five pounds. Having had a fatal result in one similar case, he would not have undertaken laparotomy if it had been possible to exclude ovarian cyst. He was unable to enucleate the entire tumor, but took away the greater portion, and closed the abdomen. The patient died. He had found the intestines in front of the tumor, a fact which lent support to the opinion that the tumor was of the kidney. The case was of interest also in the rapid growth of the tumor, and absence of any urinary symptoms. Having determined the nature of the tumor, it would have been better, he said, to tap or remove posteriorly.

Dr. Goffe said he was present at an operation by Dr. Thomas, when a tumor was removed weighing about twenty-five pounds, and Dr. Thomas remarked that it was not an ovarian cyst, as had been supposed, but a tumor of the kidney, basing the opinion on the fact that he found the intestines in front of it.

Dr. McLean added, that anterior exploratory puncture in his case would have been dangerous, since the intestine lay in front of the tumor. Besides, if fluid had been withdrawn, he thought nothing but a careful chemical analysis would have shown its nature; the kidney-tissue having been completely destroyed, he did not think there was any urine.

Delivery at Six Months and a Half; Child Viable.—Dr. H. L. Collyer reported the case. Mrs. G—— consulted him April 3, 1890, complaining of chronic cellulitis, which he treated by tincture of iodine, glycerine tampons, etc. She had been married eleven years, had had four children and one miscarriage. Menstruation was pretty regular, somewhat painful. July 5th, she menstruated as usual. August 6th, there was a scanty hemor-

rhage for three days. The third week in August, Dr. Collyer detected changes taking place in the uterus, characteristic of pregnancy in the early weeks, and pronounced her gravid. The patient then told him that conception must have occurred July 18th, for she had not cohabited prior to that time for three months. She expressed fear that she would miscarry. At intervals afterward she had bearing-down pains and spots of blood. Dr. Collyer noticed an increase in size of the right cornua of the uterus, August 23d; the uterus was elastic on pressure, as if distended by a small rubber ball at the fundus and right cornua. He had noticed the same feeling in many other cases at the fifth week. Toward the seventh week the fundus was enlarged uniformly; at the eighth week there was some softening of the cervix. He thought on several occasions that the woman would miscarry. She went on, however, until January 24, 1891, when there was profuse hemorrhage, but miscarriage was obviated until February 3d, when he delivered her of a small male child. It cried loudly. He wrapped it up, waited five minutes before cutting the cord, and then took away the placenta. The child weighed two pounds and four ounces, the toe-nails and finger-nails had not yet formed, the bones of the skull were soft, the frontal suture was still open, the testes had not descended. He wrapped it in wool and put it into a basket near the stove. It was fed on milk and water from a spoon every two hours, was oiled twice daily, and after repeated attempts was taught to nurse. It was under Dr. Collyer's observation until nine months of age, when the mother took it with her to friends in the West. The facts in the case pointed plainly to gestation of not more than six months and a half, or twenty-six weeks. He remarked that in general practice infants born even at the seventh month seldom lived, but his experience with this case would lead him to think that with an incubator and attention to be had in a hospital, it should not be very difficult to rear them when born at six months and a half.

Dr. Malcolm McLean said he had raised three or four infants born at the seventh month, in cotton wool, without a regular incubator.

The Chairman said it would have been interesting to have the evidence of the membrana pupillaris as to the early birth of the child, but Dr. Collyer replied that he had not taken particular notice of the eyes further than that they looked glairy, and not as the eyes of a child at term.

Dr. Edgar said a good deal of reliance had been placed on the length of the child in judging of the stage of gestation, the weight varied more than the length. Dr. Collyer said he had not measured this one, but thought it was twelve or fourteen inches long.

Unknown Cause of Death after a Minor Operation.—Dr. Locke reported a case which occurred a year ago in hospital practice, that of a healthy-looking Danish girl, who for four months had noticed a swelling on the vulva near the urethral orifice, and afterward two others. They caused no pain, but some hemorrhage took place between menstrual periods which did not seem to come from the vagina. The tumors reminded Dr. Locke of pictures of melano-sarcoma. They were about the size of a hazel-nut. He advised removal. The patient took ether easily, was under its influence about fifteen minutes, and then, after they had rolled one of the small tumors out of its capsule, she was noticed to be in apparent collapse. The operation was discontinued, she was restored from immediate danger, but during the afternoon the respiration became sighing, the patient became delirious, there was cold perspiration, and death took place next morning, with a temperature of 107° F. The condition of the urine had been normal, the heart normal. Some urine withdrawn after the operation showed a little albumin and few casts. An autopsy was not obtained. Ether was the anæsthetic. They were puzzled to know the cause of death. Dr. Prudden had examined the small tumors, and pronounced them simple blood-clots.

Dr. Collyer referred to a case in which a simple operation was performed for synovitis, ether being given, kidney trouble excluded; yet the temperature soon ran up to 104° F., and the patient died under circumstances similar to Dr. Locke's. He supposed there was either acute pulmonary œdema or pneumonia resulting from ether inhalation. He had given up ether for chloroform, fearing kidney and respiratory complications from ether inhalation.

The Chairman and other speakers suggested a hemorrhagic tendency in Dr. Locke's case, and possible internal hemorrhage or pulmonary embolus.

Atresia of the Vagina Following a Normal Labor.—Dr. Malcolm McLean related a case of almost complete occlusion of the vagina, following shortly upon a multipara's last labor. Up to the expulsion of the child the labor had been normal, but for some reason the placenta did not come away at once, and the attending physician stayed with the patient all night, trying to express the placenta and control hemorrhage. At last the placenta was cast off and there was no further hemorrhage. A few weeks later she found the vagina much shortened, was operated upon by two physicians who lengthened it about two inches, but did not succeed in reaching the uterus. She consulted Dr. McLean on account of a vesico-vaginal fistula. The uterus was still beyond reach, but as the patient was near the menopause, and the vagina had fair length, she wished to be treated only for the fistula. He was unable to understand the cause of the atresia.

Dr. R. A. Murray said he had known undiluted persulphate of iron to be used to stop hemorrhage, and cause cicatrices in the vagina. In the present case it was not unlikely this stypic had been employed in its full strength, and caused the vaginal surfaces to adhere together and form atresia.

The Association of Rectal and Pelvic Diseases in the Female.—Dr. Robert A. Murray read the paper, which, he said, was intended to be only suggestive, and to call forth a discussion. When he considered the intimate anatomical connection between the rectum and the genital organs, it would not seem strange that disease in one should cause disease or symptoms in the other.

Constipation, while not exactly a disease, was present in a large proportion of the cases which came under the care of the gynecologist, and was the cause of much trouble. The first symptoms present in most cases was pain in the left side over the region of the ovary, then flatulence and constipation. By recalling the anatomical relations one could readily understand why the patient should have pain in this region. The rectum lay on that side, the ovary and tube were almost in contact with it, constipation gave rise to congestion of the pampiniform plexus and vessels in the neighborhood. To relieve engorgement of these veins it was necessary to empty the rectum. The only apparent solution of posterior displacement in many virgins was pressure during defecation when there existed chronic constipation. Relieve the pressure by correcting the constipation, and the patient ceased to complain. In long-continued obstruction to the pelvic circulation caused by chronic constipation and uterine displacement we found hæmorrhoids and an inflamed condition of the lower gut. Cathartics in these cases were likely to cause greater suffering by renewing inflammatory symptoms; relief would not be experienced until the communication between the genital and portal circulations had been made free, 1, by replacing the uterus; 2, by use of rectal enemata.

In virgins chronic constipation also often caused a dragging and falling sensation in the pelvis, by giving rise to congestion and varicosity of the vaginal and uterine veins, and led in time by such congestion, and by the pressure forward of the distended gut against the vagina, to retroversion and prolapsus. In this condition correction of the retroversion did not give relief, since the starting cause was not retroversion, but rectocele. Cure the

chronic constipation, and the other symptoms would disappear. He had seen several cases in which this rectal distention had given rise to slight fissures at the entrance to the vagina, the passage of hard fæces distending the rectum and sphincter, also stretching the vaginal fissures and causing much pain. A cure of the fissures could be effected only by overcoming the constipation.

It was a common idea among women that if the bowels were free during menstruation they suffered less, and in general he believed this was true; but if a perimetritis were associated with disease of the tubes and ovaries, the patients might suffer more, the diarrhœa exciting an acute attack.

Many patients complained of a discharge of glairy mucus from the bowel, and burning sensation after defecation, perhaps accompanied by a bloody discharge, especially during the menstrual period. Relief of this catarrhal proctitis often caused relief of pelvic pains and enabled the patient to tolerate uterine disease, if it did not cure her.

Hæmorrhoids and fissure of the anus were frequently associated with uterine disease, especially where there was pressure by the displaced uterus or a tumor. When caused by pressure of the uterus, replace the organ. The patient should rest in bed, receive a vaginal hot-water douche, the hæmorrhoids should be replaced after defecation. Dyspareunia was often caused by fissure of the rectum, and disappeared with cure of the rectal trouble. Similar troubles might arise from an ischio-rectal abscess pointing in the perineum. The author had had two cases of ulcer of the rectum which he was unable to cure until he had made an incision, and then treated the case as he would one of complete laceration of the perineum.

The author thought it would be evident to all, even from the brief manner in which he had treated of the subject, that to cure uterine trouble we must also give attention to the rectum and pelvic circulation.

Dr. H. J. Boldt thought that of all subjects in gynecology the one forming the title of the paper had been most neglected. How frequently was the rectal disease overlooked! The association of rectal and uterine trouble had been found so common in his practice that he had found it advisable to examine the rectum in about four of every five cases which came under his observation. Very frequently some of the symptoms would thus be cleared up. For instance, in posterior uterine displacement, especially with fixation, one of the most prominent symptoms was aching pain along the spinal column, extending sometimes as high as the cervical region. In these cases he had found ulcer of the anterior rectal wall, about half an inch from the sphincter, almost a uniform complication. The ulcers varied in size from that of a split pea to that of a ten, or even a twenty-five cent piece. They were difficult to cure. The best treatment had been by superficial curettement after application of a strong solution of cocaine. Then use an enema of flaxseed-tea after each act of defecation, and introduce a suppository of iodoform and sulphate of zinc. Small external hæmorrhoids and fissures were common.

Dr. Florian Krug agreed with former speakers that rectal diseases associated with the uterine were common, and often were overlooked. He made it a custom to examine the rectum when symptoms pointed to uterine disease, and often found lesions which had been overlooked by other gynecologists. He would not dwell upon the commonest of all complications, constipation. Chronic enteritis, which he indefinitely located in the lower part of the bowel, frequently gave rise to symptoms which were credited to the uterine appendages. He referred to a case in which the patient had been treated by various measures —electricity, etc.—directed against supposed disease of the tubes and ovaries, and finally was told by her physician that it would be necessary to remove the appendages. When Dr. Krug saw her he could find no evidence of disease of the appendages, but found, on examining the stools, a cast of the mucous membrane of a portion of the bowel, and treating her for chronic enteritis she got well.

Dr. A. H. Goelet said that while women generally gave a story of constipation, yet some had masses of fæces in the rectum while having a passage every day. One patient consulted him for uterine trouble, in whom he could feel a tumor as large as his fist posterior to the uterus, yet so high that it could not be felt through the rectum below, the lower part of the bowel also being full. The peculiar position and mobility of the tumor led him to think it was in the rectum, yet the patient said she had had daily passages for months. He sent her home, prescribing a powerful cathartic, which caused copious watery discharges, yet on her return the same tumor could be felt in the pelvis. He managed to dislodge it, found it a fecal mass, as large as a baseball, hard enough to crack with a hammer, dry and light enough to float on water. Its removal was followed by disappearance of the "uterine" trouble.

Regarding the treatment of proctitis, he had found the most efficient means consist in introduction of the bivalve speculum after using cocaine, and dusting the mucous surface over thoroughly with powdered boracic acid.

Dr. Collyer had usually found that women had masses of fæces behind the uterus, but supposed that men, if they should be as frequently examined, would be found to have this portion of the rectum also distended. It seemed to be the receptacle for waste. He agreed with other speakers, that the rectum received too little attention compared with the uterus and its appendages. Hæmorrhoids or polypoid growths were frequently present. Especial attention should be given the lower portion of the rectum.

Dr. J. R. Goffe emphasized the remarks of previous speakers, and said that a chronic constipation often arose because women put off going to stool on account of a sensitive ovary resting on the rectum, the pain being increased by fecal movements.

After some further discussion the Section adjourned.

Correspondence.

SOME OF THE DANGERS TO WHICH EPILEPTICS ARE EXPOSED.

To the Editor of the Medical Record.

Sir: I earnestly desire to bring up before the minds of our profession the many and great risks to which patients suffering from epilepsy are exposed, especially when in public places and thoroughfares.

Going through a street in the city at a recent date I perceived a gentleman fall in a fit, and it was immediately made clear to me that the case was one of epilepsy, and from the gravity of which evidently *le grand mal.* The patient recovered in the usual manner. A fact was forcibly presented to my mind in this case, viz., that a patient who was liable to a similar attack anywhere should not be allowed to go about unattended.

Three cases of a similar description having been brought to my notice, I presume to offer the following suggestions: Firstly, that medical men insist that patients affected with this malady shall not go about in public places unless attended by someone, and to see that they are obeyed; secondly, that members of our police be instructed not to run the risk of causing asphyxiation by forcing small pieces of ice into the patient's mouth on such an occasion.

As we are certain in most cases of epilepsy of the grave type that the patient will have a paroxysm sometime, ponder if it is not something akin to neglect and carelessness if we allow such a patient to run the risk of being frightened, maimed, or even possibly killed.

Respectfully,

R. Harcourt Anderson.

THE DIAGNOSTIC VALUE OF VOCAL FREMITUS IN PNEUMONIA.

To the Editor of the Medical Record.

Sir: Having read the article in your issue of June 6th, by Dr. J. P. Rand, of Worcester, Mass., on "The Diagnostic Value of Vocal Fremitus in Pneumonia," kindly allow me to reply.

There may be cases of pneumonia in which the bronchi, large and small, are completely filled with inflammatory products, either pneumonic in character or due to accompanying bronchitis, etc. In such cases vocal fremitus may be absent. However, I assume that these cases are the exception.

The case to which the writer of the article in question refers might have been of that nature; or there were, possibly, conditions present and unrecognized which would account for the absence of vocal fremitus or the presence of a dull percussion note, or both. A circumscribed area of dry pleurisy, with fibrinous exudation, might have been sufficient to have produced dulness on percussion. A thickening of the pleura from previous inflammation, together with a central area of lung consolidation would give the same physical signs that were found in the case cited.

That the case referred to is exceptional in this particular is evident, but it is not evident that it has any bearing on vocal fremitus as a diagnostic sign in pneumonia, for, as the writer truly says, "the art of physical examination depends upon fixed laws."

The writer's analogies and comparisons are incompatible with a knowledge of the anatomy and histology of the lung and the pathology of pneumonia and pleurisy with effusion.

Lung consolidation does not mean, nor should it necessarily imply, that the bronchi are included.

Referring to Loomis for pathological information, as the writer of the article has done for physical signs, the following is found: "Not infrequently the material in the infundibula and air-cells extends into the minute bronchi, but these tubes are rarely completely filled with the pneumonic exudation."

Accordingly air may be found in the larger and smaller bronchi in the stage of consolidation in pneumonia; consequently the vibrations of the vocal cords may be transmitted through these bronchi to the point where consolidation commences, which is in the infundibula and alveoli, thence through the consolidated lung tissue to the pleura and chest-wall. Excluding cases previously mentioned, it is difficult to perceive how vocal fremitus can be absent in uncomplicated lobar pneumonia.

In pleurisy with effusion, when the diagnosis is well established, the lung on the corresponding side is not only displaced upward and backward but is also compressed, so much so as to occlude entirely, in some cases, many of the bronchi, large and small. Under such circumstances it is difficult to understand how vocal fremitus can possibly be present.

Therefore, to compare pneumonia with pleurisy with effusion, so far as vocal fremitus is concerned, is but to ignore the pathological conditions peculiar to each disease.

The specific gravity of a pneumonic lung, as compared with water or a serous exudate in pleurisy, has no bearing on the transmission of vibrations of the vocal cords in either of the conditions just named.

The analogy of the sponge and violin is objectionable, for, unless the violin-strings could be made to vibrate within a hollow tube, which was connected with numerous smaller tubes, which in turn were inserted into the meshes of the sponge, which latter should completely fill the cavity, the arrangement would be but a poor representation of the structures concerned in phonation. Air confined within a certain small space is a much better transmitter of vibrations than is air not so confined.

The writer states that he "does not assent to the generally accepted proposition that a solidified lung is a better communicator of vocal vibrations than is the healthy one." He says, "it is against reason, against natural philosophy, and, according to my limited observation, against fact."

So far as natural philosophy is concerned he is referred to his own quotation from the "Encyclopædia Britannica," viz.: "When a wave of sound travelling through one medium meets a second medium of different kind, the vibrations of its particles are communicated to the particles of the new, so that a wave is excited in the latter, and is propagated through it with a velocity dependent upon the density and elasticity of the second medium."

"It appears to be well established that while vibrations of a solid are, in general, most readily communicated to other solids in contact with it, they are not so to liquids, and still less so to air and other aëriform fluids."

The preceding paragraph has a direct bearing upon the conditions prevailing in lung consolidation, as compared with the lung in a healthy state.

In a state of health the vibrations of the voice are transmitted through the air contained in the bronchi, through the reserve and residual air contained within the lungs, to the parenchyma, pleura, and chest wall.

In pneumonia the lung is swollen and lies in closer contact with the chest-wall than it does in health; the pleura may be thickened and covered with fibrous exudation; the residual air contained within the alveoli is displaced by the products of inflammation which constitute the consolidation.

Every condition prevailing in pneumonia favors the transmission of the vibratory thrill to the chest-wall in a greater degree than do the conditions in health.

Combining reason, natural philosophy, and a fair knowledge of pathology with even a limited amount of observation, it would seem that vocal fremitus should remain, as it is, a valuable physical sign in pneumonia and some other forms of lung consolidation.

HEALTH OFFICER IN THE CABINET.

To the Editor of the Medical Record.

Sir: The judicious editorial on this subject in the last Medical Record deserves careful consideration.

A Bureau might be created under the Treasury or Interior Department, to be known as the National Medical Council, or National Board of Health, at the head of which should be placed by the President an official to be known as the Medical Director-General of the United States. This officer should be assisted by a Medical Council consisting of the President of the American Medical Association (or other representative of the profession) and the chiefs of Bureau or Surgeon-Generals of the Army and Navy. The present Marine Hospital Service might be merged in the latter, and the details in the Government services could be made by their respective chiefs on application of the Secretaries of War or Navy to the Secretary of the Treasury or Interior—under whichever department the Health Bureau was placed. The national interests of the medical profession in matters relating to the formation of State Board of Health, epidemics, etc., could be managed by the civil representative of the Council, and this scheme would *centralize* medical work, and give the necessary force and authority for its execution.

Hermes.

Medical Instruction in the University of Madrid.—It is stated that twelve of the twenty-four chairs in the medical faculty of the University of Madrid are vacant, and of the remainder four are filled by men who are unable, by reason of advanced age or infirmity, to discharge their duties satisfactorily.

New Instruments.

A MODIFICATION OF A NASAL SNARE.

By JONATHAN WRIGHT, M.D.,
NEW YORK.

Since the publication, three years ago, of a design of a nasal snare by the writer, the instrument has met with a fair amount of favor at the hands of those interested in nasal surgery. Not being a perfect instrument it is necessarily capable of improvement. Among the objections urged against it the one of most force is that, with it, it is impossible to work very slowly, which is desirable where vascular growths are to be removed. As for myself, I prefer for this purpose the cautery snare, as it has been my experience, both with my own and other kinds of snares, that you occasionally get an uncomfortable amount of hemorrhage however slowly you tighten the loops, or whatever instrument you use. Those however who prefer the cold snare, I think, will find the following device a useful change from the old pattern.

The cannula, instead of screwing into the cogged bar sheath, fits in as a plug. It is provided with a small thumbscrew to bear on the stylet when tightened. The latter runs all the way through the cogged bar, and by means of a screw at the handle end of the instrument, is held firmly in place. When the wire loop has been sufficiently tightened around the vascular growth, and it is desirous to allow the patient to wait a few minutes, the thumbscrew is used to fix the stylet in the cannula. The screw at the handle end of the cogged bar releases the end of the stylet by a single turn, and the cannula and stylet can then be quickly separated from the rest of the instrument and allowed to hang from the nose as long as desired. The process is reversed when it is desired to proceed with the operation. This may be repeated as many times as desired, and at any stage of the operation. The time consumed in detaching and attaching the stylet is very much less than that taken to describe the process.

The accompanying illustration only represents the modified part of the instrument, *i.e.*, the cannula, stilet, and cogged bar. Reference to the Medical Record of March 17, 1888, will explain the principle of the whole snare to those not familiar with it. It is a simple matter to change the old pattern to the new. Hazard, Hazard & Co. have executed the design, and of them it may be procured.

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from June 7, 1891, to June 13, 1891.

Horton, Samuel M., Major and Surgeon. By direction of the Secretary of War, the leave of absence on surgeon's certificate of disability granted in S. O. 49, March 4, 1891, from this office, is extended three months on surgeon's certificate of disability. S. O. 129, par. 6, A. G. O., Washington, D. C., June 4, 1891.

Byrne, Charles B., Major and Surgeon. With the approval of the Acting Secretary of War, granted leave of absence for fifteen days, to take effect on being relieved from duty at Fort McHenry, Md. S. O. 130, par. 14, A. G. O., Washington, D. C., June 8, 1891.

Harvey, Philip F., Major and Surgeon. The leave of absence for seven days, by Orders No. 96, c. s., Fort Keogh, Mont., is extended fourteen days. S. O. 98, par. 2, Department of Dakota, June 5, 1891.

Walker, Freeman V., First Lieutenant and Assistant Surgeon. The leave of absence granted by Orders No. 100 c. s., Fort D. A. Russell, Wyo., is extended twenty-three days. S. O. 68, par. 6, Department of the Platte, June 8, 1891.

Alexander, Charles T., Lieutenant-Colonel and Surgeon, Attending Surgeon in New York City. By direction of the Acting Secretary of War, is, in addition to his other duties, assigned to duty as examiner of recruits in that city. S. O. 132, par. 21, A. G. O., Washington, D. C., June 10, 1891.

Official List of Changes in the Medical Corps of the United States Navy for the week ending June 13, 1891.

Alfred, A. R., Assistant Surgeon. Detached from Naval Hospital, Norfolk, and ordered to the Fern.

Stoughton, James, Assistant Surgeon. Ordered to duty at Naval Hospital, Norfolk, Va.

Young, L. L. S., Assistant Surgeon. Ordered to duty at Naval Station, Port Royal, S. C.

Hochling, A. A., Medical Inspector. Ordered as member of Naval Medical Examining Board.

Street, T. H., Surgeon. Ordered to duty on the Bennington.

Wailes, P. S., Medical Director. Ordered as delegate to represent Medical Corps of the Navy to the International Congress of Hygiene and Demography at London, England.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending June 13, 1891.

	Cases.	Deaths.
Typhus fever	0	0
Typhoid fever	15	6
Scarlet fever	179	34
Cerebro-spinal meningitis	1	2
Measles	343	24
Diphtheria	80	27
Small-pox	1	0
Varicella	1	0
Pertussis	3	6
Erysipelas	2	0
Mumps	0	0
Rötheln	0	0

Drug-Stores in Russia exist to the number of 2,688, and in one year did business to the value of over $9,000-000.

The Library of the École de Médecine, of Paris, contains over 40,000 volnmes, in addition to a very interesting collection of antographs of the Deans of the Faculty from 1324 to 1789. The new building, to which the books have recently been moved, has a large reading-room which will accommodate about one hundred and fifty students.

Women Medical Students.—Of the medical colleges in this country and Canada forty six admit both men and women to their lecture classes, and nine admit women alone.

Dr. P. N. Parnowskaja, a Russian female medical practitioner, has been awarded a gold medal by the Moscow Society of the Friends of Natural Science, Anthropology, and Ethnography, for her work on the "Anthropology of Prostitutes and Female Thieves"—*Medical Press.*

A VEGETABLE PLATE; ALSO A NEW TECHNIQUE IN INTESTINAL ANASTOMOSIS.[1]

By ROBERT H. M. DAWBARN, M.D.,

PROFESSOR OF SURGICAL ANATOMY AND OPERATIVE SURGERY, NEW YORK POLYCLINIC.

It must be obvious to the surgeon who has kept abreast of the advances made of late years in bowel-surgery, that perfection has not by any means been attained in respect to plates or rings for intestinal anastomosis.

In some respects Senn's bone-plates are best. But not every surgeon has these plates, in the various necessary sizes, constantly on hand. This is a mild statement, since but a month ago one of the largest surgical supply houses in this city assured me that my order for Senn's plates was the first his firm had ever received. Then, too, they take a week or more to make, and cost $2 per pair. Another drawback is their occasional obstruction of the anastomotic opening by sliding over it after some days; for they are absorbed with rather objectionable slowness.

These reasons, mainly, have led investigators to devise ready means of substitution; and the number of additional rings or plates already before the medical world is nearly a dozen.

Of these, the most prominent are the following:

1, Abbe's catgut rings; 2, Brokaw's segmented rubber rings (of tubing filled with catgut threads); 3, Robinson's plates of fresh hide; 4, Matas's solid catgut (drum snare) rings; 5, Davis' solid catgut plate: also his catgut mats.

Among all of these there is not one which can truthfully (after studying its method of preparation) be called an emergency method save No. 2, which to this extent is the best; and sometimes No. 3. As the latter (raw hide) is not by any means always obtainable on a few minutes' notice, it can only at times enter this list.

All of the catgut methods save No. 4 have the double objection that they swell greatly in any watery solution—such as the semi-liquid fæces—and, as Senn alleges, have sometimes thus produced dangerous pressure at the points of ligation; and further, that they quickly soften within the gut and lose all rigidity. This anyone can prove by putting an Abbe ring (for example) in water at the bodily temperature for even one hour.

Let us now suppose a clinical case in surgery. Suppose we as surgeons are called on unexpectedly to deal with a strangulated hernia. Our medical brethren have, following their custom, delayed sending for the man with the knife until a late hour in the case. Suppose we find, upon opening the sac, a loop of dead gut; not doubtful, but dead Assume that the patient's general condition is a fair one—enough so to warrant a half hour longer under ether.

In such a case, which is common enough, most surgeons would prefer excising the dead gut and restoring sound continuity, rather than making an artificial anus.

But now, which of the various plates and rings can be prepared in a few minutes to meet this pressing want? Hardly Abbe's rings:—made off-hand, and without preliminary soaking and untwisting in warm water, they do not make smooth pressure and they twist badly. These particular objections do not obtain against his rings of course, if they have been previously prepared. Not Matas's drum-snare rings; they must be boiled, and otherwise prepared. Not Davis's catgut plates, nor his catgut mats, obviously. The Robinson plate of green hide could occasionally be quickly made. More often it would not be procurable.

The segmented rubber ring of Brokaw would meet our requirement fairly well as to speed, but is open to the objections mentioned as against any catgut method. Then, too, this last plan is inferior to some plate, because apposing a narrower peritoneal surface than would a plate. If (as has been suggested to overcome this objection) several of Brokaw's rings be made, each of such a size as to fit neatly inside the last, and all to be sewn together so as to make a mat with a central opening—this will take considerable time.

The field, then, seems open for a really good emergency plate; and the plate of raw vegetable tissue is the one I have to recommend. I have experimented for some months, and used many kinds of raw vegetable and fruit tissue. That which I like best, for several reasons, is raw potato.

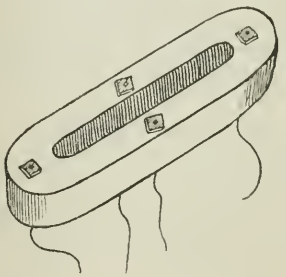

Fig. 1.—The potato plate ready for use (threads short and needles omitted).

During many weeks past, by the courtesy of Professor John G. Curtis, I have operated upon a large number of dogs in his physiological laboratory, at the College of Physicians and Surgeons, New York, and have experimented to a lesser extent at the N. Y. Polyclinic; and I present to you for your examination some dozen or so specimens, taken from as many dogs upon whom the potato plates have been recently used. My first dog died from faulty technique—the plates I made were too large for his diminutive guts. Since then I have had but one death from leakage, in simple excision of a loop of intestine, followed by lateral anastomosis in this method; and only two additional deaths from any cause whatever. The last sixteen dogs operated upon by the new technique have all lived until I chose to kill them, after several days to several weeks, in order to demonstrate the results.

I have to thank Drs. F. J Brockway and H. G. Myers for kindly aid rendered in many ways during this work, which is still being continued. But I have cause to feel satisfied that plates cut from raw potato are abundantly worthy of trial; and that they are probably, considering all things, the best of the aids to anastomosis, whether for emergency work or for that performed after deliberation. By their help, and with the new technique later to be described, a simple enterectomy with lateral anastomosis is, in dogs, almost sure of recovery.

[1] In part, read at a special meeting of the Surgical Section of the New York Academy of Medicine, held April 27, 1891.

For use upon the human gut the plates should be made about one-third inch in thickness, or for added rigidity even a trifle more. The calibre abundantly allows this. In the smaller and thicker-walled bowel of dogs, they should be rather thinner, and like Senn's bone plates, ¼ inch. To prevent the thread from cutting through, we should have it very coarse, make a large knot, and before sewing through the plate sew through a scrap of rubber cut from a drainage-tube; or, lacking this, a minute bit of cloth. The plates should be cut so long that the opening shall be about twice the normal diameter of the gut to be operated upon. This is in the line of safety, because a long slit insures easy passage of fæces from the first, and consequently avoids strain on the sutures. And also, experience shows that an ultimate contraction of the new hole to even half its original size may occur—may even be expected.

It is not claimed for the potato plate—nor I think for any plate or ring save (possibly) Senn's—that it can safely be trusted to coapt peritoneum by its four or six stitches alone, without additional sutures outside. Indeed, I believe that the best that should be said of any of these aids is that after their application the necessary sutures—Lembert or other—can be much more speedily and neatly applied; and speed is a tremendous factor in success in bowel-work. Still, the raw potato plate is very rigid, and retains rigidity considerably longer than any of the catgut methods. This is easily proven. Put the raw potato plate, together with the rings, for comparison, into simple warm water; into warm water plus pepsin and hydrochloric acid; and into warm water plus extract of pancreas and alkali. The vegetable plate will remain fairly firm long after the others have become flabby and useless.

Experience shows that it is best not to immerse the potato in carbolic solution before use, as when this is done the plate softens more quickly, at the same time turning pink.

Regarding the question of digestibility, I have specimens taken from the middle of the small gut in dogs showing that at the end of forty-eight hours the potato-plate is intact, though shrunken and soft; at the end of three days is also broken here and there; at the end of five days, has utterly disappeared. It seems probable that in similar regions of man its digestion would be quicker; since man is omnivorous, while the digestive fluids of the dog are presumably those meant for a carnivorous diet mainly.

In one specimen, from a dog killed thirteen days after using these plates, in lateral anastomosis of colon to colon, the potato was found broken, shrunken, and softened, but still in place. A ball of hair on the proximal side, allowing fæces to pass only with difficulty, may have, been a partial cause of slow removal in this instance, though the region—the colon—would perhaps sufficiently account for it.

In another singular case, one of lateral enterostomy in the middle of the small gut, the plates were found, after twelve days, shrunken and somewhat *hardened*, but broken into several pieces. In this animal, too, a ball of hair was present, and may have protected them somewhat from contact with intestinal juices.[1]

In a case of gastro-enterostomy (dying from my failure to cover in at one point an anchor-stitch) the stomach-plate was found entirely gone at the end of three days. Its intestinal fellow was represented by but a few scraps stained yellow with bile.

To sum up, the advantages claimed for the vegetable plate are as follows:

1. It may be made a real emergency method, being by far the speediest of all. I have made a pair of plates, with threads in place and ready for use, in ten minutes.

2. The potato can be procured anywhere without delay, and without cost.

3. It is a plate, and safer than a ring, because keeping in contact a wider peritoneal surface than a ring can do.

4. A very long ellipse, which is best, is easily made and maintained; some fleshy roots other than potato may by their length permit plates to be cut with extremely long apertures. This, however, can rarely be needed.

5. Unless withered and shrunken potatoes are used there is no tendency whatever to swelling, with its consequent danger from pressure, as against the catgut method.

6. It is rigid and remains so a longer time than the catgut rings. I generally soak the peeled potato for an hour or two before use; because, although with a sound potato the plate does not perceptibly swell nor change size, *it grows even harder in water for a time;* while in air, by drying, it becomes more flexible and soft.

7. One of the dangers of the bone-plate is its slow absorption, with possible sliding so as to obstruct the new opening. If a plate by its presence will aid speedy application of a line of sutures, and will then keep the denuded surfaces quiet and in contact for just a few hours, that is all we want of it. And the sooner thereafter it disappears, the sooner a possible source of danger is removed. If surgeons will only remember to *scrape well with a knife* the surfaces to be coapted, they need not ever fear a lack of rapid plastic exudation. To aid perfect quietude of the guts during this period, the critical one, I would insist upon the invariable use of as large a hypodermatic injection of morphine as the patient can safely bear.[1]

Regarding the application of these or any other plates or rings for lateral anastomosis of gut to gut, preceded by excision of a portion, the following is the technique which I would recommend as being the best. I give it in detail; in part it is new.

Assume that the dead or diseased region is cut away, being careful to sacrifice what is even suspicious; that the gut is temporarily closed with (in emergency) boiled tapes, six inches at least from each open end; and that thorough irrigation of the mucous surfaces has cleansed them of all apparent filth. (Mem.—The human gut can easily be turned mucous side out, over a finger, for a very considerable distance, thus aiding efficient cleansing.) Our needles, after threading, are tied by a single knot in the eye, to prevent loss of time by accidental unthreading. The four threads are each about twelve inches long, from the plate to the needle. Following Carson's suggestion, they may be two black and two white, although I have never had the least delay or confusion with threads all black. The needles should all have their points buried in bits of potato, each at least the size of a pea. Now,

1. Seize a needle with the needle-holder so that it shall be in the long axis of the holder. Begin with the one marked A in the accompanying diagram (Fig. 2). Pass the needle several inches into one of the open gut-ends, bringing it out through the potato on its point, and then gut-wall at the desired place, which should also be directly opposite the mesentery. Draw its thread through for a few inches. Now, with one or two fingers inserted within the intestine, seize and withdraw the scrap of potato on the thread (or else invert the gut over the finger, thus exposing it). Break the potato off the thread. Now pass needles B and C in the same way. After each thread is passed it should be held by an assistant tense against the wall of the gut on the side where it belongs, and the next needle should carefully run along the opposite wall; this to avoid tangled threads.

[1] It has occurred to me that if the fleas which so regularly infest street-dogs were killed, the dogs would not have the same incentive to gnaw their hide; and would not thus accumulate the hair which, collecting in the bowel, so annoys experimenters. A bichloride bath once or twice should prove effective.

[1] This free use of morphine has unquestionably helped to secure my large percentage of success in dogs. They are peculiarly insensitive to morphine in any moderate amount; and in even small dogs I regularly begin by a hypodermatic injection of a grain to a grain and a half of sulphate of morphine. Following this they need but little ether—sometimes none—and vomit less than otherwise. Such doses seem hardly to affect them more than ten minims of Magendie's solution would affect a man. (Here let me remark that by free use of analgesics I have always avoided causing suffering in the dogs experimented upon.)

It would, of course, be easy to vary the technique here by detaching the bit of potato with the fingers, through the gut-wall, when the right point is reached by the needle, instead of sewing through it, etc. But in that case these pieces might get between the plate and the mucous surface of the bowel and cause irregular pressure in that way. Hence the direction just given.

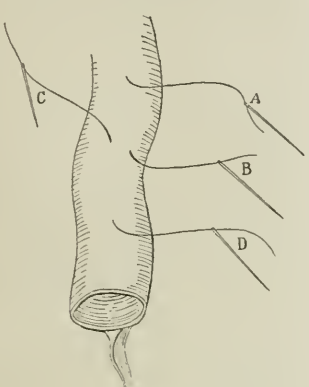

FIG. 2.—A plate in place and ready to tie to its fellow.

In the small intestine of dogs, owing to thick and comparatively rigid gut-walls, and to the absence of valvulæ conniventes, the pieces on the needle points, while a convenience, are not so necessary as in human intestine.

2. Pull lightly on threads A, B, and C, while pushing the plate from behind, drawing it thereby into place within the gut. Push, rather than pull, to avoid oblique tension on the threads and possible cutting of the plate. Next pass D and draw it also taut.[1]

3. Go through the same steps with the other plate and the other gut-end. Always leave *a full two inches* between the plate-end and the gut-end in each instance.

4. Wipe off the threads with a cloth wet in some antiseptic solution.

5. Scrape lightly but thoroughly, with a scalpel, the surfaces to be coapted. This is a most important step; and the scraping is better in every way than scratching with a needle, as a means of insuring rapid plastic exudation over the entire coapted region. The scraping requires but a few seconds. Upon the living gut each stroke is followed instantly by a somewhat congested surface, differing strikingly in appearance from the unscraped; so that it is easy to know when the desired region has been so treated.

6. Tie the four anchor [plate] threads each to its appropriate fellow, being careful to draw snugly, but not to force the pressure. The open ends should first be pointed in opposite directions. (This Abbe has recommended, although he has also obtained satisfactory results with the ends directed alike.)

7. Run at least one line of sutures around the plates, being extremely careful to cover in and hide completely the four anchor-stitches; also, though the threads must enter the muscular coat to avoid danger of tearing out, yet the utmost caution must be exercised never to penetrate the lumen of the gut with any thread save the four plate-threads, which must necessarily go directly through the wall. *Here, if anywhere, the beginner will cause a fatal result. He will insert his needle too deeply.*

If preferred, the line under discussion may be of interrupted sutures, in which case Halsted's square stitch is unquestionably the best. Personally I rather prefer, and can apply nearly equally quickly, two lines of continuous suture, three stitches to the inch. It is not wise to attempt more than three to the inch. If the thread dives beneath the peritoneum for a shorter space than one-third inch, then, as it must to avoid penetration go very superficially, it is likely to cut out when tightened. Fig. 3 shows the method which I have now employed in about twenty cases. The second line should entirely conceal the first line, just as the first hides the anchor-threads.

Extremely simple as this method is (a basting-stitch) and doubtless well known to many surgeons as a stitch, I have not found it described among intestinal sutures. Those resembling it most nearly are, so far as I can ascertain, the spiral suture of Nuncianti and the method of Gély.

I prefer it for two reasons. First, speed. Running as it does parallel with the plate-edges, it is much more quickly applied without danger of sewing too deeply than is the Lembert (in which the needle is made to enter at right angles with the line of proposed union), or for that matter than any interrupted. Two rows can be applied in nearly the same time as one interrupted. Second, safety. It would be almost difficult by this particular plan to draw the thread so tightly as to threaten sloughing. Also, if the old technique be used (that in which the side of the gut is opened to give entrance to the plate) then by this stitch one is less likely than by the Lembert to drag out, while passing it, the gut edge from between the plates accidentally. The second row of this continuous line should be so applied that where in the first row it went above the line of union it now goes below. (See Fig. 3.) Passing both rows with speed and safety will be notably facilitated if an assistant first presses the plates firmly together and draws the gut tightly and smoothly over them meanwhile.

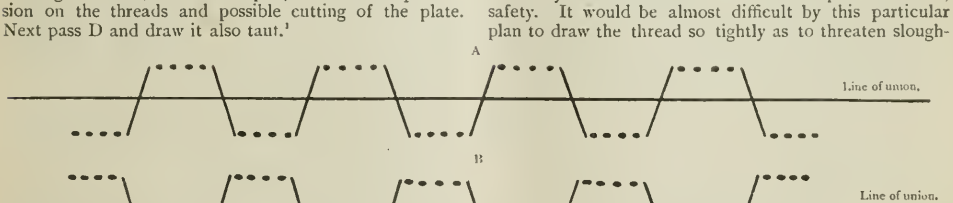

FIG. 3.—A, First row; concealing carefully the four anchor stitches. The dotted lines indicate the concealed portion of the suture. B, Second row; nearly one quarter inch farther from plates; concealing carefully the first row. Note that where A ascends B descends, and *vice versa*. The stitches in the sketch are, for clearness, drawn only about half the actual number to the inch.

To continue our new technique:

8. Run into one open gut-end a thin strip of wood, like cigar-box, or perhaps pasteboard, as wide as the potato-plate. This is to cut against.

9. Now we make our opening through the apposed and sealed gut-walls. To do this, insert a scalpel or a sharp-pointed bistoury into the other open gut-end, and cut through between the plates, carefully, making as long an anastomotic opening as the plates will allow. The strip of wood opposite prevents cutting too deeply.

In dogs, a special knife is needed for this stroke, which must in them be made blindly, guided by sense of

[1] I am not at all sure that it would not be an improvement in technique to do away with the two side-threads connecting the plates and retain only the two end ones. The anchor-threads are unquestionably an element of danger, and this is reduced one-half by the plan suggested. Of course the plates would then not be held firmly together at the sides; but, after all, we rely for our protection mainly upon the surrounding lines of suture, placed later.

touch and position of handle. I use on them a gum-lancet, sharpened on both borders as well as its hatchet-edge. But in human gut, fortunately, it is easy (the wall being much thinner), to slide the two inches of open end along, and—an assistant holding the end open with thumb-forceps—then make the cut with an ordinary knife, *seeing the whole length of the stroke*. If preferred, for safety, the blade may be wrapped with adhesive plaster or thread down to a half-inch from its point. Should bleeding follow, it could easily be controlled by forceps; but this is unlikely to happen, both because the cut is made directly opposite the mesenteric attachment, where the vessels are smallest, and also because the moderate pressure of the plates would tend to check it. By the action of the powerful circular muscles, as soon as anæsthesia is ended, the line of incision gapes as widely as the plates permit.

10. Remove the knife and also the strip of wood. Irrigate. If the cut is properly made, the water should run freely into one end and out of the other. Under gentle hydrostatic pressure, closing the outlet end with finger and thumb for a few moments, the line of suture should not leak if properly made. *This is a valuable means of safeguard and should never be neglected.*

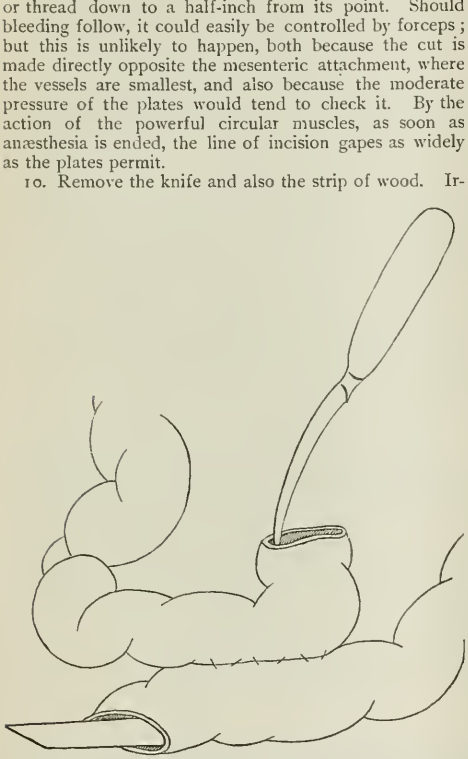

FIG. 4.—The suturing about the plates is completed; the anastomotic opening is being made; in short lines the outer row of sutures is indicated roughly.

11. Now scrape the peritoneum, and then invert one free end with a pair of dressing-forceps, carrying the intussusceptum far enough in to touch the plate. Close the peritoneum over the inverted end with two rows of the kind of running suture already described. (One row would perhaps suffice here. The long intussusceptum proves a decided protection against leakage. In dogs I have never had the least trouble with the ends, using one row only.)

12. If the surgeon, after inverting the end and before withdrawing the forceps, will transfix gut and intussusceptum with one or several needles, to be left in place until the sewing of the end is completed, he will find this step much facilitated. Do the same with the other end.

13. Take a stitch or two between the blind ends and the gut against which each should rest, first scraping lightly. This prevents possible forcing of another loop into this angle, with resultant undue tension on the stitches at the plate ends; an accident which led to leakage in one of my first experiments on dogs. It is also a safeguard against intussusception into the new opening, which has been observed by one worker in this field (Robinson).

14. If desired, apply an omental graft. I have never used these, being well pleased with the results obtained without them, and wishing, also, to avoid prolonging the operation. Further, I have desired that these new plates should have a crucial test, without unusual aids to union.

It takes a long while, as you have doubtless observed, to describe these details, but the actual application is quite brief, and indeed more so than by the plans in use heretofore.

For the sake of clearness fourteen steps have been itemized. This is not unnecessary elaboration. Success in these operations is a question of care, even unto the minutest particulars. Life or death will hang upon the tension of a thread.

I have, without extreme haste, done lateral anastomosis by this method, including tying off mesentery and excising several inches of gut, in half an hour, counting from the first stroke in the belly-wall to knotting of the last suture in the belly-wall. Of this period about twenty minutes were devoted to the bowel itself. I have no doubt that this time could in case of need be shortened several minutes.

The following points will be noted as new in the technique just advised for use with any plates or rings:

a. The method of inserting the plates and making the anastomotic opening.

b. The method of suturing.

c. The method of denuding peritoneum to hasten plastic exudate.

d. The method of protecting the sutures at the plate-ends by causing adhesion of the blind ends to the adjacent bowel.

e. The method of retaining the inverted ends by transfixion with needles while sewing these ends.

The first has the following advantages, readily appreciable by anyone who has tried other plans: Safety to patient in that the peritoneal surfaces are apposed and sutured before being opened; hence less danger of septic infection in the line of stitches.

I have compared this method, too, by actual trial, with that whereby Senn prepares a double row of Lembert stitches, then opening the side of the gut for entrance of the plate as usual, etc. The method herein given is unquestionably safer regarding infection.

Everyone knows who has done this work the constant annoyance (greater of course in dogs than men) from rolling out of the cut edges, largely due to the action of the powerful circular muscular layer. This nuisance is hereby done away with, as also is the dangerous tendency to sepsis, as well as loss of time, from pulling out the cut edges from between the plates, unintentionally, while passing the line of protecting sutures. All work about the plate should be definitely concluded before the anastomosis is made. Speed is also gained through avoiding loss of time in the various annoyances mentioned.

Among the greater advantages of this new technique is the opportunity to test readily by irrigation the perfection of our barrier of sutures and plates. This is, of course, impossible by the old plan. Just as it is advisable to do this after suture of the urinary bladder, so it is here. The time to discover a possible leak is at this moment, rather than on the autopsy-table.

I take it quite for granted that most surgeons will agree with me that the day of circular enterorrhaphy (save for very exceptional cases) is past. Work in that line is work almost thrown away. This plan has not, so far as I am aware, a single advantage over lateral anastomosis; and it has several fatal defects. I was sorry to see a very able experimenter, in an article in the *Annals of Surgery* for February, spending time over what he calls a "stove-pipe" method, whereby the distal end is deprived of its mucous surface for half an inch or more, and then the proximal end is inserted, a long rubber tube being within both.

This, while easy on the thick gut of dogs, is not easy on the very thin human intestine. In the lower half of the small gut of man the entire thickness of all six or seven anatomical layers composing its wall is so trivial that a newspaper placed within can be read.

Furthermore, any circular method necessarily, from the very beginning, makes a smaller opening than the normal; and even this is bound to shrink. Such methods, too, threaten leakage at the deadly mesenteric junction. They are difficult where removal of a considerable length—more than a few inches—leaves sound ends of differing calibre. By any "stove-pipe" method, such as Jobert's or Robinson's, mistaking the proximal for the distal end would be fatal; and though Nothnagel's salt test seems an unsafe guide, we do not wish, in a herniotomy, to start at the cæcum and handle perhaps ten or fifteen feet of gut to make sure which end is proximal! By the bye, if much is removed, the proximal end can be recognized by its being, in any part of the bowel, down to the rectum, the larger in calibre (that is, of course, comparing large with large and small with small gut). This fact, too, is against any stove pipe plan, since the big end would have to be inserted into the little one. No time is saved by the circular enterorrhaphy as compared with the lateral anastomosis just described. And finally, in favor of the latter method, it makes no difference thereby which is the proximal end or what the relative calibres.

Of late the German school of surgeons have made what I believe to be a distinct backward step in casting aside all plates, rings, etc., and trusting solely to suturing without such aids. Their objection thereto is certainly a weighty one. The threads whereby such plates or rings are connected have passed first through a fæces poisoned mucous membrane and then the peritoneum. This fact, together with the liability to subsequent infection by capillarity, cannot be denied.

But a point upon which I insist in the present paper is that these plate-stitches must be *covered in* by the continuous or interrupted layer or layers outside, which latter do *not* enter the lumen of the gut. And if this is done the relative danger of infection is but trivial, since, if suppuration should occur at the primary stitch-holes, the pus, following the direction of least resistance (the softened plates not opposing), re-enters the interior of the gut.

In everything we do as surgeons and physicians we have to choose the lesser evil; and it is, I firmly believe, a lesser evil to use plates by the technique which I have just described than to attempt to do without them, thereby necessitating a longer operation with its perils. Speed, let me repeat, is a tremendous factor in success in peritoneal work.

I have conscientiously tried almost all methods that have appeared in the journals during the past five years, in my operative surgery classes. In that time I have certainly demonstrated enterorrhaphy upon human cadavera by one or another method at least one hundred and fifty times, and in addition have experimented considerably on dogs. And I am satisfied that the method herein advocated, in all its details, is the safest of any with which I am acquainted.

A Protest Against Licensed Prostitution.—A memorial has been presented to the Japanese Parliament, praying for the abolition of licensed prostitution in the empire. It is contended by the petitioners that the system encourages immorality, debases woman, and promotes, rather than hinders, the spread of venereal disease. There never was a measure, the memorial states, which showed more plainly the sex that devised it than this system of license, and never one which showed more the brutal side of man's nature. It is a scheme to protect man in his baser impulses at the expense of woman; and society is corrupted in the effort.

Clinical Department.

FOREIGN BODY IN THE LUNG.

By E. G. EPLER, M.D.,
FORT SMITH, ARK.

While assistant physician at the Cook County Infirmary, Chicago, Ill., the following case came under my observation:

August W——, a native of Sweden, forty years old, was admitted August 7, 1884, for lung disease. But little could be learned of his past history.

He complained of frontal headache, fever, pain in the right side of the thorax, and cough, with expectoration of heavy yellow sputa. Dyspnœa was marked. Respiration jerking and irregular. The inspiration was quick and sharply ended. The expiration was prolonged. Pain at times was excruciating. Copious hemorrhages from the lungs occurred frequently.

On physical examination the heart was found to be normal. Auscultation of the lungs revealed fine crepitant and submucous râles over the right lower lobe, anteriorly and posteriorly. Coarse râles were heard throughout the other portions of chest. Percussion was painful over the lower lobe of the right lung. Marked dulness was elicited at this point, but the resonance was normal over the remainder of the chest. The patient gradually failed, dying July 20, 1885, nearly one year after his admission.

Post mortem Examination.—The heart was normal. The bronchial mucous membrane was granular in appearance and congested. Otherwise, the middle and upper lobes of the right lung and the entire left lung were normal. The lower lobe of the right lung was solid, and was firmly adherent to the thoracic walls. In detaching it the lung-tissue was torn. A cavity filled with clotted blood was found in the lower and posterior part of this lobe. In the midst of the clot was found a rusty piece of metal, similar to the clips used in certain batteries for the purpose of closing the circuit. It was 2½ inches long by ½ inch broad, of the thickness of writing paper.

How the foreign body had become lodged there is a mystery. There was no cutaneous scar, nor evidence of a wound of the œsophagus. It must have passed down the trachea.

A FIVE INCH HAIR-PIN IN THE POSTERIOR NARES.

By M. W. KELLIHER, M.D.,
PAWTUCKET, R. I.

On Thursday, May 28th, I was called to see a young lady, aged twenty, who said that the day previous she had swallowed a pin. She said she had been to three physicians, and was told that it was imagination on her part. Upon examining her throat I, too, thought that imagination was her highest prerogative. She insisted, however, that she swallowed a pin.

Upon questioning her in regard to the size of the pin, she said it was a regular-sized hair-pin. She said that she thought she felt it in her nose that day. I now felt more incredulous than before. However, I inserted a probe into the right nostril and found that there was a foreign body in the posterior nares on that side. I was able to mark out one prong of the hair-pin, but the end was inserted into the mucous membrane of the nasal bone. After some difficulty I was able to catch it with a long, slender forceps. Where the other prong of the hair pin was located I could not find out. However, I thought I would risk it, and make traction. I succeeded in getting one prong about one-half inch through the right anterior nares when in the meantime the other prong came through the right nasal bone close to the inner canthus of the right eye. I then removed the hair-pin by pulling it through the right nostril. It was a regular-sized hair-pin, measuring about five inches from point to point.

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

New York, June 27, 1891.

THE CAUSE OF DIPHTHERIA IN RURAL DISTRICTS.

DR. LONGSTAFF, in a recent voluminous work on "Statistics, Social, Political, and Medical," makes an interesting study of the causes of diphtheria, more particularly, of course, as it occurs in Great Britain. He finds that it is a disease of the country rather than the city. Thus for every 1,000 deaths from the disease in dense districts there are 1,178 deaths in medium districts, and 1,507 in sparse districts. With regard to specific causes Dr. Longstaff says: "The cause or causes should not be sought for, primarily, in any high development of civilization, such as sewers, but rather in some condition associated with more primitive modes of life. Again, privies and ash-pits can hardly be important agents in breeding or disseminating the disease, or we should expect to find diphtheria exceptionally prevalent in those northern towns where such nuisances reach their worst, whereas the contrary is the case. On the other hand, low vegetable organisms developed in damp dwellings would perhaps fit in with the facts that I have brought forward; or again, some evil special to shallow wells, or other primitive sources of water-supply. The line of investigation, however, which seems to me most promising, lies in comparative pathology. The peasantry live on intimate terms with domestic animals, more particularly cows, sheep, pigs, and poultry (including pigeons). Some little known disease of some one or other of these creatures may be capable of inducing in men or women, brought into frequent or close contact with them a trivial 'membranous sore-throat;' then under suitable conditions of recipient and environment, the more generally recognized form of the disease, 'true diphtheria,' or, as it used to be called, 'cynanche maligna,' may result. The poison, perhaps gathering intensity and infectiveness, may then be conveyed into towns by farm produce, such as milk, cream, or poultry, conceivably by eggs, meat, or vegetables; and lastly, through the persons first infected, the sources of water-supply or the public sewers may get poisoned, and so, indirectly, aid in the spread of the disease."

The suggestion is one that country practitioners should bear in mind. At the same time it is quite possible that the lessened death-rate from diphtheria in large cities is due to a superior sanitary organization.

FATHER MOLLINGER'S FAITH-CURE.

THE phenomena of faith-curing, mind-curing, and similar exhibitions of human credulity have become so common as to cease to be interesting. Their history is nearly always the same, the psychological process is identical whether it be some holy well in Canada, or some fashionable mystic on Fifth Avenue. A recent illustration of faith curing by a Catholic priest near Pittsburg, Pa., however, presents some novelties. The priest in question, Father Mollinger, is, we are told, deaf, rheumatic, and neurasthenic; nevertheless he has acquired an enormous fame for curing those and other maladies. This he does, however, not only by his prayers and blessings, but by giving medicine also. His work represents the potency of faith and drugs combined. They worked so well and gave him such a reputation that his very success was the cause of his undoing. The climax of Father Mollinger's power was believed to be reached on St. Anthony's day. At that time hundreds of people travelled to his church from all the country round, and even from distant places. Hemiplegia, paraplegia, rheumatism, phthisis, epilepsis, cases of blindness, deafness, and all sorts of chronic ailments were brought to the priest. The numbers were so great as to tax the capacity of all means of conveyance, and the church was full and surrounded by a riotous mob of anxious and faithful seekers for health.

The result is best told in a despatch from Pittsburg published the day following: "The misguided sufferers who fancied that they had but to be blessed by Father Mollinger to be relieved of their afflictions are now returning in carloads to their distant homes. Many go away crippled in body, ruined in pocket, and in despair instead of hope. The reaction is so great that the sight the disappointed present is most touching.

"There passed through the Union Station to-day several hundred maimed, halt, and blind persons, who were returning home after a week of prayer at Father Mollinger's chapel. None of them had been relieved in the slightest manner, and many were suffering severely in consequence of the exposure to which they had been subject. Several women who live in the eastern part of the State were brought to the Union Station on litters or stretchers, because they were too ill to sit up. A number of men who had been able to walk with the aid of crutches when they came to Pittsburg had to be wheeled through the station to the day express in armchairs. They had broken down under the strain and the disappointment."

The story of Father Mollinger would prove what we have always asserted, that popular faith-cures and miracle-cures do more harm than good. It is very well to infuse hope and courage into the sick; it is wise to try and change the mental condition of the hypochondriacal and nervous; but it is almost exclusively on cases of this kind that faith works well. And if we must have miracle-cures they should be prescribed by a physician, like baths, massage, and pills.

A SUPREME COURT DECISION OF INTEREST TO PHYSICIANS.

IT is not often that the Supreme Court of the United States is called upon to decide a question of special interest to medical men as distinguished from other patriotic

citizens, but such a question was decided not long ago. The ruling was on the right of a railway company, when sued by a person who has sustained injuries, to have such person examined by its own surgeon.

A woman sued the Union Pacific Railroad Company, in the Circuit Court of Indiana, on account of an injury of the spine, which she claimed had resulted from the fall upon her of an upper berth in a sleeping car. Three days before the trial the company asked the court for an order requiring the woman to submit to an examination by the company's physician, the examination to be made with as little exposure of the person as possible and in the presence of the physician of the injured woman. The court overruled this motion on the sole ground that it had not the legal right to enforce such an order. The case came before the Supreme Court on the correctness of this ruling, and the latter sustained the lower court, saying that such an examination is an invasion of the sanctity of the person to a degree that the law does not recognize, and that it is inconsistent with the common law. The opinion said that the court could not find that until within a generation it ever was thought that a court of common law had such a power as was claimed in this case.

Justices Brewer and Brown dissented from this ruling. Justice Brewer said that actions for damages for personal injuries, now so common, were very infrequent years ago, and that it was therefore an open question, and one not determinable under the old common-law procedure. If a person permitted exposure for the purposes of examination by the physicians who would be called to testify in her behalf, it seemed to him but common justice that an order should be made to permit examination by the opposite side. He did not think it right that any person, after making disclosures of the person where her interests were promoted, should be allowed to refuse this permission to a physician representing the company sued, on the plea of sanctity of the person.

We would not presume to decide which of these conflicting opinion is the better law, but it is easy enough to see which has the most justice and common-sense on its side.

THE USE AND ABUSE OF DENTAL CHARITY.

A very interesting paper with the above title was presented by Dr. Richard Grady, of Baltimore, to the Section of Oral and Dental Surgery at the meeting of the American Medical Association in Washington in May. It seems that our dental friends have not been as wide awake to their own interests as they should have been, and now they find that, like their medical brethren, they have allowed their colleges to establish dispensaries, one after the other, "for the relief of the indigent poor and the instruction of students," until the time has now come when they realize that these same dispensaries are treating the well-to-do as well as the really deserving, and taking the bread out of the mouths of their own graduates for whose interests, as students, it was claimed that the infirmaries were established.

It is only recently that this abuse has attained such proportions as to alarm the members of the dental profession, and this protest of Dr. Grady is, we believe, the first that has been made publicly against the constantly growing evil. The Maryland Dental Protective Association was organized in Baltimore, in February, a year ago, its object being to regulate the administration of dental charity, but thus far nothing has resulted from the movement except the adoption of a resolution calling upon the dental colleges to insist upon the giving of aid to the really indigent only, which resolution, as far as heard from, has not yet effected the desired reform.

The author of the paper had informed himself very carefully as to the conditions of infirmary treatment in the different dental colleges of the country, and had found that abuses existed in nearly all, though in varying degree, some discriminating against patients who appeared to be in comfortable circumstances, others taking everybody that came along in their scramble for clinical material. One college had adopted a truly unique method "to discourage well-to-do people by making charges a little higher than those ordinarily made in offices." Inquiries had also been made among dentists in the larger cities as to the effect upon practice of the competition with the colleges, and the answers to these inquiries were, as was to be expected, that the injury done to the younger men in the profession was a very real one. The colleges advertised for patients, setting forth in glowing terms the excellence of the workmanship and the extreme reasonableness of the charges, and thereby at once gained an advantage over the individual dentist, who was debarred by professional opinion and the fear of forfeiting the respect of his associates from advertising in a similar fashion.

But it is not so much the facts presented by Dr. Grady, as it is the manner in which his hearers received his paper, to which we wish to direct the attention of our readers. The paper was discussed after it had been read, and again the following day, its discussion having been made the regular order for that session. The result of this was the unanimous adoption of a resolution that "the Section would suggest to the National Association of Dental Faculties the importance of some action toward correcting any existing abuses of the charities connected with dental colleges or schools." We are glad that the dental surgeons have taken this matter up with the intention of doing their best to right the beginning wrong, and we wish them the greatest measure of success in their crusade. And we wish this not alone for their sake, but also because, if they succeed, it may give heart to those of the medical profession who are trying to secure for their younger brethren the means of a decent livelihood by freeing them from the unjust and ruinous competition of the dispensaries and clinics which take so many patients that should belong to the private practitioner.

The Washington State Medical Society held its Second Annual Meeting in Seattle, on May 6th, 7th, and 8th. The meeting was largely attended, and a number of interesting papers were read. The following officers were elected for the ensuing year: *President*, Dr. H. C. Willison, of Port Townsend; *First Vice-President*, Dr. G. W. Libby, of Spokane; *Second Vice-President*, Dr. H. P. Tuttle, of Tacoma; *Secretary*, Dr. Elmer E. Heg, of North Yakima; *Treasurer*, Dr. James B. Eagleston, of Seattle. The next meeting will be held in North Yakima, Wash., beginning the second Wednesday in May, 1892, and will continue for three days.

News of the Week.

The Late Dr. Fordyce Barker.—The New York Academy of Medicine mourns in Dr. Fordyce Barker the loss of one of its oldest members, who, for six successive years was its President, and by his peculiar traits of character, and the interest he displayed in the success of its work, contributed largely to its development and rise. His earnestness of purpose secured for him the respect of his fellow-practitioners, his teaching the esteem of large audiences, his writings the appreciation of the medical profession both in our country and abroad, and the never-disturbed kindliness of his disposition and his incomparable urbanity of manner the admiration of hosts of friends. His departure will long be deplored, both by his medical brethren and the public; and long will he be missed on the floor of the hall of the Academy which he graced by his very presence.

A. Jacobi, M.D.,
William T. Lusk, M.D.,
A. A. Smith, M.D.,
Committee.

Esteem for Dr. Barker in England.—At a meeting of the London Gynecological Society, on June 19th, Dr. Barnes moved a vote of condolence with the family of the late Dr. Fordyce Barker, who was an honorary member of the society. Dr. Barnes spoke of Dr. Barker as a man honored by all. He had never known a man more generally beloved. Dr. Phillipson seconded the motion. He remarked that to say that America had lost one of her most illustrious physicians was to express very imperfectly the sense of their loss. The memory of Fordyce Barker would long be revered and cherished. The motion was unanimously adopted.

The Will of Dr. Fordyce Barker.—By the will of the late Dr. Fordyce Barker, the New York Academy of Medicine is to receive all the works in his library relating to obstetrics, gynecology, and the diseases of children.

The Late Dr. Fordyce Barker.—The *British Medical Journal* pays the following tribute to the memory of our late colleague, Dr. Barker: "For many years he was a regular visitor to our shores. Everyone who had once seen his handsome face, beaming with bright intelligence and kindness of heart, longed to see him again. At the annual meetings of our Association he was often present and always welcome. This feeling found cordial expression in the titular honors showered upon him by our societies, colleges, and universities. It is a long list to draw up. Not one who looks over our academical rolls but will recognize his name with pride and affection. We cannot now describe all his work. His book on puerperal fever charms by its style, while it instructs by the richness of experience and the soundness of its reasoning. He was, we believe, connected with Dr. Fordyce, who holds so prominent a place in the history of English medicine. The portrait of Dr. Fordyce was treasured in his house. All who were acquainted with Dr. Barker were familiar with his peculiar utterance—a hoarse whisper, but still very distinct. It was the result of paralysis of the vocal cords. This defect in no way impaired his power as a speaker or lecturer. His classes at New York were well attended. He was a popular and effective teacher. He leaves a widow, who traces her descent from Pitt, our great statesman. Her personal qualities, inherited and reflected, endeared her to many friends. He leaves also an only son, who holds an eminent position in the States."

Fordyce Barker, M.D., LL.D., was born at Wilton, Me., May 2, 1818, his father having also been a member of the medical profession. He was graduated from Bowdoin College, Brunswick, Me., in 1837, and from the Bowdoin Medical School, May 12, 1841; having passed a year in Boston in the hospitals under his preceptor, Dr. Henry I. Bowditch, by whose advice he selected his new home carefully, as he had a tendency to pulmonary disease. Finding that Norwich, Conn., met this need, he located there in the summer of 1841. From being the youngest he soon rivalled the best-established physicians. Dr. John Gray, of Mystic, was his first medical student (and was present at the funeral services at Norwich, June 3, 1891). He married September 14, 1843, and his wife survives him. In 1844 the way opened for carrying out Dr. Bowditch's wish of 1841—that he should study for a French degree. He left this country for Havre, France, October 1, 1844, from New York. The winter was devoted to hard study, following the hospitals, and attending lectures. He passed June and July, 1845, in travel, but was recalled unexpectedly in August by the severe illness of a loved relative. His diploma was afterward sent to him. Baron Dubois, Trousseau, and Sir Joseph Oliffe were among his friends. He resumed practice at Norwich, September, 1845, and was soon known throughout the State. A paper that he read (at Hartford) before the Connecticut Medical Society attracted much attention. In 1846, at the age of twenty-seven, he was elected Professor of Midwifery at Bowdoin Medical School. He filled the chair but one year, finding that the needed absence interfered with his practice. In 1848 or '49 he was visited by Professor Chandler F. Gilman, with reference to removal to New York. Subsequent events led to his locating in this city in 1850, leaving a large and valuable practice. Here he became a member of the Faculty of the New York Medical College in East Thirteenth Street, and subsequently of Bellevue Hospital Medical College. He belonged to the latter at the time of his decease. He had also been a member of the Bellevue Hospital Medical Board, and the only survivor of the governors who appointed him is the Hon. William M. Evarts. He was a member of many leading societies, both medical and literary, in this country and in Europe. He was the recipient of many honors. He held the presidency of the New York Academy of Medicine from 1878 to 1884, and did much for its prosperity. He received the honorary degree of LL.D. four times—on June 12, 1878, from Columbia College, New York City; on April 17, 1884, from the University of Edinburgh at its tercentenary celebration; in June, 1887, from Bowdoin College, his Alma Mater; and on August 10, 1888, from the University of Glasgow. A fifth LL.D. was offered him by the University of Bologna, Italy, at one of its great anniversaries, but he was unable to attend. His discrimination and judgment led prominent lawyers to seek his aid, and he was often

retained by them in difficult cases. In the celebrated Guiteau case he at first refused to testify; but on the receipt of a personal request from President Arthur, consented. He only saw Guiteau in the court-room when giving his calm opinion as an expert. It was said that it had much influence with the jury and the Attorney-General. His reputation was world-wide, and his friends many in both American and European cities. He was not only honored as a great physician, but as a Christian gentleman, a ripe scholar, a genial companion, a loyal friend. Among his patients have been many whose names are familiar, one of them being General Grant. All that medical skill could do was done for him in his short illness, Dr. Anderson coming to him at once, and Drs. Thomas M. Markoe and Dr. William H. Draper meeting Dr. A. A. Smith in consultation. But naught availed to keep him here. On Saturday, May 30, 1891, his earthly life closed, and he entered into rest. He leaves a fragrant memory with his profession and with his countrymen.

The American Society of Microscopists will hold its fourteenth annual meeting in Washington, D. C., August 10th, and continue in session five days. Its roll of active members contains about three hundred and fifty names, the membership consisting of professional men and students of the natural sciences, who use the microscope in their daily avocations as an instrument of research, diagnosis, or precision, and amateurs. In its earlier years the latter predominated in the membership of the society, but at present the professional element is largely in excess. The qualifications for membership are very simple. The applicant must be a respectable person socially, and interested in the use of the microscope. The dues are $2 per annum, and the initiation fee $1. Applications for membership should be made to the Secretary, Dr. W. H. Seaman, No. 1427 Eleventh Street, Washington, D. C. The application should be accompanied by $3, which is the initiation fee and one year's dues.

The Medical Association of Central New York held its Twenty-fourth Annual Session at Buffalo, N. Y., June 2, 1891. It was largely attended, and a long but interesting programme was disposed of under the efficient presidency of Dr. Nathan Jacobson, of Syracuse. The following officers were elected for the ensuing year: *President*, Dr. Alvin A. Hubbell, of Buffalo; *First Vice-President*, Dr. Louis A. Weigel, of Rochester; *Second Vice-President*, Dr. Henry L. Elsner, of Syracuse; *Secretary*, Dr. Edward B. Angell, of Rochester; *Treasurer*, Dr. Alfred Mercer, of Syracuse. Hereafter one meeting of the Association will be held each year, the time chosen being the first Tuesday of June. The meetings will be held in Buffalo, Syracuse, and Rochester in rotation. The next one is to be held in Syracuse.

The Association of Military Surgeons.—The regular meeting of the Association of Military Surgeons of the Wisconsin National Guard, was held in Milwaukee, June 20, 1891. The proposed meeting of the Surgeons of the National Guard of the United States, which was to have been held in Chicago next July, has been postponed until September. At that time every effort will be made to organize an Association of Military Surgeons of the National Guard. So far, about four hundred have expressed a willingness to attend. Judging from the correspondence received, the organization of the association is assured. At its first meeting papers will be read by Surgeon-General Bryant, of New York N. G.; Surgeon-General Yandell, of Kentucky N. G.; Surgeon-General Senn, of Wisconsin N. G.; Surgeon-General of Illinois N. G. The association will be entertained in Chicago by the local Guard.

Dr. Bacon's Golden Jubilee.—The following resolutions were adopted at the Annual Meeting of the Oswego County Medical Society on June 9, 1891:

Whereas, Dr. Charles G. Bacon, of Fulton, N. Y., aged seventy six, and whose connection with the Oswego County Medical Society the records show to have been since the year 1841; and

Whereas, The proceedings of this Society show his continual presence and participation each and every year for the past fifty years without a break or excuse; and

Whereas, He has occupied every office in the gift of this Society, and for most of the time being its financial banker and treasurer; therefore, be it

Resolved, That we round out the Semi-Centennial of Dr. C. G. Bacon, and declare him most cordially and unanimously elected our presiding officer for the ensuing year; and

Resolved, That the Secretary be authorized to send a copy of the above to the MEDICAL RECORD and the *Journal of the American Medical Association* as a direct challenge to any county or state society to beat this record.

The Johns Hopkins Co-educational Medical College.—Miss Mary Garrett has contributed an additional $10,000 to the endowment fund of the proposed Johns Hopkins Medical School, says the Baltimore correspondent of the *Journal of the American Medical Association*. In a letter dated April 27th, addressed to President Dobbin, of the Board of Trustees, she makes this offer payable October 1, 1892, subject to the following conditions: That by February 1, 1892, the trustees raise the remainder of the sum necessary to bring the endowment up to $500,000—the minimum limit proposed by the trustees—and further that the trustees shall give notice in February, 1892, that they will open the school in October, 1892, and shall actually open it then. The committee of ladies organized to raise $100,000, having accomplished their object, has disbanded. The following represents the present status of this endowment: The entire sum raised by the committees of ladies of Baltimore and elsewhere and paid over to the trustees May 1st was $111,000; there were already in hand additional funds sufficient to raise this amount to $178,780. In order to avail of Miss Garrett's offer, it is therefore necessary to raise $221,219. The trustees have accepted her offer and have resolved to endeavor to raise the balance required. Of the $111,300 raised by the ladies, Baltimore contributed $68,882; the next largest contribution was Boston's, $20,231, and Philadelphia's $8,075. If the ladies would only raise $200,000 to endow some medical college already in existence it would do a vast deal more good. The college in this city, for example, would be enormously helped by it.

The Association of German Alienists will meet this year at Weimar, on September 18th and 19th

St. Francis Hospital, New York.—Dr. August Siebert has been appointed Visiting Physician to St. Francis Hospital.

Sir Prescott Gardner Hewett, a distinguished English surgeon, died in London, June 20th. He was one of the Sergeant Surgeons to Queen Victoria and surgeon in ordinary to the Prince of Wales. He was educated at St. George's Hospital in London, and subsequently took a complete course in surgery at a Paris school. He became a member of the Royal College of Surgeons in 1836, was elected an honorary Fellow in 1843, and a member of the Council in 1867. He succeeded Sir James Paget as President of the Royal College in 1876, and in 1883 he was created a baronet.

The New York College of Physicians and Surgeons.—We have a little more exact information in regard to the union of the College of Physicians and Surgeons with Columbia College, which has not hitherto been published, than we had at our last issue. It is true, as we supposed, that the old College found that even the gifts of the Vanderbilt family were not sufficient to enable the Faculty, with all the fees of their large classes, to run the institution in a proper manner. Doctors have borne deficits enough in New York City for the sake of honor and fame, and we suppose the Faculty of the College of Physicians and Surgeons were not willing to make up the large sum necessary to furnish advanced medical education in the beautiful buildings so generously given to them. The seven regular professors are to receive $7,000 a year, not $7,500 as we stated, and this arrangement is to last for ten years. The Medical Faculty have the right of nominating persons to fill vacancies in their departments. It has not yet been settled as to whether, under the union, the new faculty shall be called the Faculty of Physicians and Surgeons or the Faculty of Medicine. Certainly, as we said before, the union is a great gain for medical education in this country. In one medical college, at least, the Faculty may dare to be thoroughly independent in dealing with students.—*The Post-Graduate.*

A Maternity Hospital in Sitka.—The lying-in woman in Southeastern Alaska is not a person to be envied, for she would seem to have received rather more than her share of the curse recorded in Scripture as having been pronounced over woman. One of the native customs in that part of the world is to turn a woman who is about to become a mother out from her home, providing for her only a small, rude shelter of boards, bark, or canvas as a protection from the weather and from public observation. In one of these desolate little huts, on the cold, damp ground, the Alaskan babe is ushered into the world and the mother suffers unattended by skilled nurse or physician. The child is half washed, greased, and speedily rolled up in a skin or blanket, which is padded with dried grass or moss. The little pappoose thus bandaged, is better cared for than the mother, who has even less proper attention, or more that is improper, and the chances of accident or disease on the mother's part are much greater than in the case of the infant, although the latter is often short-lived. Recently an effort has been made by some of the citizens of Sitka to provide better accommodations for native women during the period of their confinement, and through the exertions of Dr. Thwing and others a plan has been matured and some funds have been obtained for the erection of a building in the native village to be used as a lying-in hospital, and to be known as the St. John's Maternity of Sitka. One of the residents has given a plot of ground, and donations enough have been received from friends in Sitka and in Brooklyn to allow the purchase of lumber for a small building. It is hoped to obtain native labor free to erect part of the house, but foremen will have to be hired and money must also be paid for the painting and plastering and also for the beds, stoves, and other furniture. The projectors of the hospital hope to finish the building before the winter, and to enable them to do this they need more money. Any who desire to help may send their contributions to the following gentlemen, who have consented to act as trustees for the hospital, and will cheerfully acknowledge any gifts, however small: Lieutenant Emmons, executive officer of the United States gunboat Pinta; Mr. Edward de Groff, agent of the Pacific Coast Steamship Company; Dr. Clarence Thwing, physician to the Mission Hospital, Sitka.

A New Building for the Medical Department of Tulane University.—Mrs. Richardson, wife of Dr. T. E. Richardson, of New Orleans, has given $100,000 to the medical department of the Tulane University to erect a new building. A site has been purchased on Canal Street and Dr. Touchar has been delegated to visit the Northern medical colleges, as a representative of the faculty, to investigate them, and to suggest the proper sort of building to be erected.

The Berlin Municipal Council has decided to confer the freedom of the city on Professor Virchow, on the occasion of his attaining his seventieth birthday. The great pathologist's portrait will also be hung in the Council Chamber.

Dr. Liébault, the founder of the Nancy hypnotic school, was presented a few days ago with an *objet d'art*, as a testimony of esteem for his talents. A number of foreign medical men are among the subscribers to this testimonial, some of whom were present at the banquet given to Dr. Liébault.

An Unrecorded Symptom of Pertussis.—Among the premonitory symptoms of whooping-cough authors mention conjunctivitis with excessive lachrymal secretion; but according to Dr. Huguin, of Tourteron, to these ocular symptoms there should be added photophobia, with dilatation of the pupil, which he has observed pretty constantly in cases under his care, and that in the absence of all medicinal treatment, by belladonna or otherwise.

A New Dispensary Building.—The new building of the Eastern Dispensary, now called the Good Samaritan Dispensary, was opened for public inspection recently. It is at the corner of Broome and Essex Streets, one block from the old building at Grand Street that has been occupied for years. The new dispensary cost $133,000.

State Aid to Medical Education.—There is a prospect that the State of Pennsylvania will give the Medico-Chirurgical Hospital $70,000, to enlarge its buildings; the legislature has passed the bill which only awaits the signature of the Governor.

Reviews and Notices of Books.

Wood's Medical and Surgical Monographs for April. Contents: "Treatment of Syphilis of the Nervous System," by Julius Althaus, M.D., M.R.C.P. London, Senior Physician to the Hospital for Epilepsy and Paralysis, Regent's Park. "Railway Injuries, with Special Reference to those of the Back and Nervous System in their Medico-legal and Clinical Aspects," by Herbert W. Page, M.A., M.C. Cantab., F.R.C.S. England, Surgeon to St. Mary's Hospital, Lecturer on Surgery at its Medical School, Consulting Surgeon to the Cumberland Infirmary, Examiner in Surgery University of Cambridge. "Causes and Prevention of Phthisis," by Arthur Ransome, M.D., M.A., F.R.S., Honorary Physician to the Manchester Hospital for Consumption and Diseases of the Throat. Pp. 283. Single copies, $1; per year (published monthly), $10. New York: William Wood & Co.

Space will not permit extended review of the April "Monographs." All three of the essays are masterpieces of master hands. The names of the authors alone are vouchers for the book's excellence. Professor Ransome's essay on "Phthisis" is remarkably good, and deserving of careful study. His division of the subject is an index of its character: "Pathology and Affinities of Tubercle," "Topography and Distribution of Phthisis," "Predisposing Causes of Phthisis," and, lastly, "Prevention of Phthisis."

Ninth Annual Report of the State Board of Health of the State of New Hampshire, for the Year ending October 31, 1890. Pp. 343. Manchester: John B. Clark.

Dr. Irving A. Watson has compiled an interesting and valuable report, which contains considerably more than the usual dry statistics. There are articles on "The Prevention and Cure of Disease," "Dangers from Adulterated Foods," "Sewer gas Poisoning," and "Phthisis."

Thirteenth Annual Report of the State Board of Health of the State of Connecticut, for the Year ending November 30, 1890. With the Registration Report for 1889, relating to Births, Marriages, Deaths, and Divorces. Pp. 522. New Haven: Tuttle, Morehouse & Taylor.

The vital statistics of this volume are unusually complete, and there are many other features which make it of value, among them some excellent remarks about typhoid fever, a report on epidemic influenza, and articles on poisoning by illuminating gas and adulterated food. Professor C. A. Lindsley, M.D., of New Haven, is the efficient secretary of the Board of Health.

Examinations by the State Board of Health of the Water Supplies and Inland Waters of Massachusetts. 1887-90. Pp. 857. Illustrated. Boston: Wright & Potter Printing Co.

This bulky volume is devoted to the subject of Water Supply and Sewerage, and the matter is most exhaustively and scientifically discussed. Thomas M. Drown, M.D., Chemist of the Board; G. H. Parker, Biologist; and F. P. Stearns, C.E., Engineer of the Board, contribute the several articles.

Transactions of the Iowa State Medical Society for the Year 1890. Held at Des Moines, April 16th, 17th, and 18th. Vol. VIII. Pp. 307. Cedar Rapids, Ia.: *Daily Republican* Printing and Binding House.

The profession in Iowa is up to the times, and the book in hand contains a great number of excellent papers, and the reports of a number of very interesting cases.

Historical Sketch of the University of Maryland School of Medicine, 1807-90. With an Introductory Chapter, Notices of the Schools of Law, Arts and Sciences, and Theology, and the Department of Dentistry, and a General Catalogue of Medical Alumni. By Eugene Fauntleroy Cordell, M.D. (Class of '68). Illustrated. Pp. 218. Baltimore: Isaac Friedenwald.

The title of Dr. Cordell's book is a good index to its contents. It is a valuable addition to the history of Baltimore, and one that is of especial interest to the medical profession. There are contained excellent pictures of the members of the present faculty, and of some of their famous predecessors.

Practical Treatise on Electricity in Gynecology. By Egbert H. Grandin, M.D., Chairman Section on Obstetrics, New York Academy of Medicine; Obstetric Surgeon, New York Maternity Hospital; Obstetrician, New York Infant Asylum, etc.; and Josephus H. Gunning, M.D., Instructor in Electro therapeutics, New York Post Graduate School; Gynecologist to Riverview Rest for Women; Electro-Gynecologist, Northeastern Dispensary, etc. Illustrated. Pp. viii., 171. New York: William Wood & Co. 1891.

This unassuming, but excellent, manual is pervaded by an admirable tone of conservatism which distinguishes it from others on the same subject that have appeared during the past three or four years. Unlike many of the over-enthusiastic electro-therapeutists, who claim that no pelvic disorder can resist the potent agent, the claims of which they urge, the authors present, in a simple and unbiassed manner, its limits as well as its capabilities. Such an attitude is especially attractive to the thoughtful general practitioner, who is often at a loss as to which of the many hobbies he should ride. The book consists of six chapters, the introductory one, of fifty-four pages, being devoted to theoretical considerations and descriptions of apparatus; the second, of nearly equal length, deals with the routine uses of electricity, as applied to the treatment of amenorrhœa, dysmenorrhœa, subinvolution, pelvic pain, and disease of the adnexa. The authors are avowed supporters of the electrical treatment of early ectopic gestation, and present a short, but excellent, *resumé* of the most recent views on this subject. We agree most emphatically with them in preferring the continuous to the interrupted current, as less likely to cause rupture of the sac.

Electrolysis of fibroids (which we believe should be relegated to experts) is fully dealt with in Chapter III., which is fully and clearly illustrated by no less than thirteen cuts, most of which are original.

Static electricity, the galvano-cauterization of cancer of the uterus, and the application of electricity to obstetrics are subjects which receive each a separate chapter—brief, but comprehensive.

The tone of the book, as we said at the outset, is moderate and far removed from pugnacity. The authors are well known to be men with positive opinions, yet these are nowhere presented in an offensive manner, and there is not a single sentence to which even the bitterest opponent of gynecological electro-therapeutics ought to take exception. The style, though condensed, is clear and forcible. There are no less than seventy illustrations, the majority new, and all well executed. Typographical errors are unusually few, and in its *tout ensemble* the work does great credit to the publishers.

The Philosophy of Tumor Disease: A Research for Principles of its Treatment. By C. Pitfield Mitchell, Member of the Royal College of Surgeons, etc. Pp. 263. London: Williams & Norgate. 1890.

This suggestive little book is in effect a careful study of the etiology of neoplasms, based upon a careful study of clinical facts. The conclusion of the introductory chapter is that "the process by which tumors are generated by the tissues is a process of asexual genesis conditional

upon the decline of tissue-vitality;" hence the corollary that "a tumor is a local disease—local by the derivation of its elements, and local by the conditions of the derivation."

Chapter II., on "Morphology," is an exposition of the subject, in which the author seeks to show that "neoplasia is a reversion to the genesis of unicellular organisms." We cannot, in the space allotted, follow the learned writer throughout a course of reasoning in which, with true Darwinian spirit, he generalizes only after having paved the way by a solid masonry of patiently collected facts; suffice it to say, that, unlike many theorists, he does not bend them to his own uses, but subjects them to a rigid analysis.

The chapter on "The Secondary Phenomena of Tumors" is devoted to the interpretation of the expressions "innocent" and "malignant" as applied to neoplasms. "Innocence," we read, "goes with mature development, malignancy with immature development in the cell-elements of tumors."

While the pathologist will be especially interested in the theoretical portion of the book, the practical deduction of the two concluding chapters are of great importance to the surgeon. Excision is the only treatment for malignant growths, and if practised early should be curative. "From the nature of cancers and sarcomas—being offspring of the tissues—their resolution by drugs given internally is not to be expected; nor is there good evidence that any attempt ever made to cure the disease in this manner has been availing." The doctrine of heredity is rejected as based on insufficient evidence. It must be confessed that the final chapter, on "Prophylaxis," is of necessity rather vague and unsatisfactory.

The Physical Diagnosis of the Diseases of the Heart and Lungs, and Thoracic Aneurism. By D. M. Cammann, B.A. Oxon., M.D., Attending Physician in Class of Heart and Lungs, Demilt Dispensary; Visiting Physician to the Orphans' Home and Asylum, etc. Illustrated. Pp. 188. New York and London: G. P. Putnam's Sons. Knickerbocker Press.

This little work is the study of physical diagnosis in a nutshell. It is unusually complete for so small a work, and, besides the bare details of the subject, contains an interesting study of the cause of râles; whether they arise in the lungs or pleura. The author, who is a most expert diagnostician, writes in a terse, pleasing, forcible manner. His arguments for the necessity of studying acoustics are convincing. The little book contains also the averages of the measurements of the heart by auscultatory-percussion from tables made by the author's father, the late Dr. G. P. Cammann, inventor of the binaural stethoscope. The figures have not heretofore been published in full.

A Guide to the Clinical Examination of Urine. By Farrington H. Whipple, A.B. Harv. Pp. 200. Boston: Damrell & Upham.

This little work is a condensation of larger works, and purports merely to present the subject in a more readily accessible and practical form. Busy practitioners haven't the time for the large works, and to them this admirable epitome will be of great service. The author writes well and shows clear discrimination in his choice of material. His application of urinalysis to diagnosis is unusually good.

Koch's Remedy in Relation Specially to Throat Consumption. By Lennox Browne, F.R.C.S. Ed., Senior Surgeon to the Central London Throat, Nose, and Ear Hospital; Author of "The Throat and Nose, and their Diseases," etc. Illustrated. Pp. 114. Philadelphia: Lea Brothers & Co.

This is a valuable addition to the already prolific literature on the subject of Koch's remedy. It is written in a calm, scientific way, and will do much to help decide the ultimate position of "tuberculin." Thirty-one cases of laryngeal tuberculosis, treated according to Koch's method, are presented, with the author's deductions. He considers the remedy of sufficient value to warrant him to persevere in its employment, "provided always that due caution be exercised not only in the selection of patients for its application, but also in every detail of its administration." There are fifty original engravings and diagrams, and the work is of value from other stand-points than the one concerning the Koch remedy.

Society Reports.

KENTUCKY STATE MEDICAL SOCIETY.

Thirty-sixth Annual Meeting, held at Lexington, Ky., May 27, 28, 29, 1891.

Address of Welcome. — An able address of welcome was made by Dr. David Barrow, chairman of the Committee of arrangements. The report of the treasurer, Dr. James B. Kinniard, of Lancaster, showed the finances of the Society on a sure foundation, and the report of the permanent secretary, Dr. Steele Bailey, of Stanford, showed that gentleman had been conducting his office with the usual ability and energy.

President's Address.—The address of the President, Dr. George W. Beeler, of Clinton, had strains of tenderness, humanity, sentiment, and poetry. McDowell, Jenner, Dudley, and Koch were given tributes, while Henry Clay was not forgotten.

The Reciprocal Relations of the Public and the Medical Profession was the subject of a popular address delivered by Dr. Lyman Beecher Todd, of Lexington. He told of the noble deeds of the noble medical profession of Kentucky. As a star of the first magnitude, shone the history of Ephraim McDowell. He paid a tribute to the memory of Mrs. Crawford, of Boyle County, Ky., who was the patient first operated on by McDowell. Her courage was wonderful, and the conversation between her and Dr. McDowell was repeated as it took place before the operation. He had nothing to offer her. No favorable case reports, no anæsthetic. He could only tell her that he had never done the operation before, had never seen or heard of its being done, had no instruments especially made for it, and could promise her nothing. He thought this woman was a wonder, and recommended that a monument be erected to her memory. The doctor then went on and described the great benefits resulting from abdominal surgery. He dealt of the treatment of the insane, and recommended women in charge of women's wards. His remarks were well chosen, well delivered, and especially well received.

The following ex presidents occupied seats on the platform: Drs. W. H. Wathen, J. A. Ouchterlony, and L. S. McMurtry, of Louisville; A. D. Price, of Harrodsburg; Pinckney Thompson, of Henderson; J. N. McCormac, of Bowling Green; C. H. Todd, of Owensboro; H. M. Skillman, and L. B. Todd, of Lexington.

The Officers Elected were as follows: *President*, Dr. Hawkins Brown, of Huestonville; *First Vice-President*, Dr. B. L. Coleman, of Lexington; *Second Vice-President*, Dr. John Young Brown, of Henderson; *Treasurer*, Dr. J. B. Kinniard, of Lancaster; *Board of Censors*, Drs. B. W. Stone, of Hopkinsville; Charles Mann, of Nicholasville, and S. W. Willis, of Winchester. Louisville was chosen as the place of the next meeting; time not decided on.

After a hot debate it was decided to publish a volume of transactions, and in consequence the membership fee was raised to three dollars per annum.

Vital Statistics of Kentucky was the subject of a paper by Dr. T. B. Greenley, of West Point, Ky. The doctor lamented the bad condition of affairs in this line in Kentucky, and queried how long it should be permitted to continue. He advocated burial permits, notification of contagious diseases, and registration of births.

Dr. J. N. McCormac, of Bowling Green, made a practical speech in accord with the paper read.

The Progress of Medicine was the subject of a paper by Dr. B. L. Coleman, of Lexington, in which the heredity of consumption was given prominence. The paper was discussed by Drs. Thompson, Larrabee, and Palmer.

Dr. Neet, of Versailles, offered a resolution urging the legislature to build an inebriate asylum.

Dr. Pusey, of Louisville, discussed the care of the insane in Kentucky, and criticised severely the overcrowded condition of the asylums.

A banquet was given by the Lexington and Fayette County Medical Society at the Phœnix Hotel, at which two hundred and fifty persons sat, most all being medical men. Dr. Henry Martin Skillman, of Lexington, presided in an elegant manner. The menu was an excellent one, and was completed before the toasts were begun. These were as follows: "The Ministry," by Rev. Dr. W. H. Felix, of Lexington; "Our Guests," by Dr. Charles H. Todd, of Owensboro; Hon. John Young Brown, of Henderson, Democratic candidate for Governor, spoke, on "Let Him who has Won the Palm Bear it;" "Our Ex-Presidents," by Dr. John A. Ouchterlony, of Louisville. "The Law" was to have been responded to by the Hon. W. C. P. Breckenridge, but he was prevented from being present by the sudden death of his cousin, Judge Samuel Breckenridge, while making a speech at the Presbyterian General Assembly, at Detroit, that same day. "The Medical Profession a Public Trust," was the subject by Dr. Joseph M. Matthews, of Louisville. Judge James H. Mulligan spoke wittily and well from the topic "Our Commonwealth." "The Ladies," was responded to by Dr. Orin B. Todd, of Eminence; "Medical Progress and Heroism," by Dr. Dudley S. Reynolds, of Louisville; "Our Medical Sisterhood," by Dr. A. M. Cartiledge, of Louisville.

A most enjoyable reception was given by the ladies of Lexington at the Phœnix Hotel, followed by a ball.

A dinner to doctors' wives was given by Mrs. Dr. B. L. Coleman, of Lexington, which was in opposition to the banquet to which the ladies were not invited, or rather crowded out by the men.

The Report on Abdominal Surgery was made by Dr. L. S. McMurtry, of Louisville. He thought the great advance in abdominal surgery has been made along the line of greater accuracy in diagnosis, earlier and improved operations, and a better selection of cases. A very important advance is the modern conception of peritonitis. Formerly the treatment commenced and ended in opium and poultices; now we know that when the disease is not traumatic it is septic. Idiopathic peritonitis is a myth. He advised the limitation of the curette, sound, and intra-uterine stem pessaries. He wished to show that peritonitis was not of itself a disease, but arose from infection through various channels.

Dr. Skinner did not think the sound necessary, that the organs of the pelvis should be replaced without the use of the sound.

Dr. W. H. Wathen, of Louisville, was pleased at the character of the report of Dr. McMurtry. The fault with the general practitioner is that he does not pay enough attention to the pelvic manipulation, and he frequently mistakes pelvic trouble for uterine, and he thus increases instead of allaying the trouble. If we use asepsis or antisepsis we will not have trouble after using the sound. If careful, intra-uterine application is not dangerous. Good pelvic work is one of the greatest triumphs of surgery. Bad pelvic work one of the stigmas. He uses antiseptics outside of the abdominal cavity, but none inside.

Dr. J. G. Carpenter, of Stanford, thought that the more the uterine sound was used the more patients there were for the abdominal surgeons. He thought the man who was able to diagnose could do it without the use of the sound.

Dr. J. N. McCormac, of Bowling Green, thought that the operation for appendicitis was very much abused. He cited the cases of two doctors. One was given up to die and not operated on. The other was not so bad and was operated on. The first recovered, the second died. Opening the abdomen is a very simple operation. Anybody can do it. It is the final results we want. He wished to enter his protest against reporting cases and omitting funerals.

Dr. E. R. Palmer, of Louisville, thought there was no term in medicine so much abused as that of thorough antiseptic precautions. He had seldom seen them.

Dr. A. M. Cartiledge thought general practitioners should be taught to do laparotomies, for they must do them sometimes.

Progress in Obstetrics was the title of a paper by Dr. Turner Anderson, of Louisville. He thought whatever of substantial progress could be, must be placed to the credit of antiseptic midwifery. Measures for the prevention of puerperal fever lead the van. The recent report of the Sloane Maternity shows only one death out of 1,000 deliveries, due to septicæmia. Since the introduction of antiseptics in midwifery the mortality has become almost *nil*. To place obstetrics in general practice on the same footing with these maternities is the great desideratum. To do this we must abandon auto-infection and acknowledge that puerperal infection is due to contagion from external sources. The doctor gave a detailed statement of the antiseptic rules observed at the Sloane Maternity. He considered the most essential item in the obstetrician's armamentarium a bottle of bichloride tablets.

Progress in Practical Medicine was the subject of a paper by Dr. B. L. Coleman, of Lexington. The doctor thought he could not better introduce his subject than by giving a short synopsis of the natural history of the micro-organisms on which the germ theory is founded. The Koch treatment of tuberculosis came in for a share of consideration. An important contribution to the study of cerebro-spinal meningitis is made by Fron and Uffreduzzi. They claim in every case to have found a micro-organism which they believe to be the essential factor in the disease, and which is called by them diplococcus lanceolatus. It is identical with the salivary septic microbe of Pasteur, Strassburg, and Klein, as also with the diplococcus pneumoniæ as described by Fraenkel. Very considerable progress has been made in the management of the gastro-intestinal diseases of children, viz., by irrigation of the stomach, dislodging the micro-organisms, and destroying with germicides or antiseptics. Salicylate of bismuth is a remedy growing in favor. The State has not been visited by any wide-spread epidemic during the past twelve months, except by la grippe. No treatment has probably surpassed acetanilide and salicylate of sodium, either combined or separate, followed by a few doses of quinine after the acute symptoms have subsided. Especially was this suitable in neuralgic and myalgic types of the disease.

The Treatment of Lupus by Methylene was the subject treated of by Dr. M. F. Croomes, of Louisville. He reported three cases which were successfully treated by from one to thirty applications. He used the application every morning, which formed a thin coating over the lupus. The patient was well in thirty-five days.

Rachitis Infantalia was discussed by Dr. J. A. Larrabee, of Louisville. He thought the ammoniated citrate of iron in a bitter infusion was better than the ingestion of phosphates. This disease is closely related to an acid condition of the prima via, and it is very necessary to correct this.

An interesting report on "Diseases of the Rectum" was made by Dr. J. M. Mathews, of Louisville. Report of "Brain Surgery" by Dr. W. L. Rodman, of Louisville.

The Significance of Wry-neck in Otitis.—Dr. Radsach says that wry-neck occurring during an attack of otitis media indicates the presence of mastoid disease.

INDEX.

A

Abscess, 579; chronic, of the abdominal wall simulating malignant intra-peritoneal tumor, 132; cold, treatment of, 204; of the liver, treatment of, 318; treatment of, 604.
Abortion, accidental, treatment of, 633; habitual, treatment of, 286.
Abdominal cavity, plugging the, 262.
Abdominal section, elevation of the pelvis in, 137.
Abdominal surgery, 634; modern, 65.
Abdominal tumor in a male, 232.
Abdominal viscera, relation of displacement of the, to pelvic disease, 636.
Abdominal wall, chronic abscess of the, simulating malignant intra-peritoneal tumor, 132.
Accomplice, an involuntary, 668.
Acetone-yielding substance in normal urine, 205.
Achorn, J. Warren, Koch's five original cases, 77.
Aconite poisoning, a case of, 521.
Adenitis, cervical, 148, 661.
Adhesions, pleuritic, frequency of, 293.
Advertising, doctors and, 192.
Africa, a new disease in, 683.
Air-thrombus, death from, 244.
Alabama, medical law in, 463, 491, 538; State Medical Association, 520.
Albany, typhoid fever in, 174.
Albumin in the urine, source and significance of, 207.
Albuminuria, in apparently healthy people, 578, 710; in apparently healthy people, and its relation to life insurance, 669; in children, 137; proteids found in the urine in, 167.
Alcohol, a counterblast to, 630; in candy, 576; physiological experiments on the effect of, 600; use of, 331.
Alcoholism, chronic, strychnine in the treatment of, 548.
Allen Charles W., tenement-house schools, 66.
Aloes, the Wiesbaden elixir of, 666.
Alumni Association of Charity Hospital, first anniversary dinner, 321.
Alumni Association of the Woman's Hospital in the State of New York, 115.
Amblyopia, alcoholic, and tobacco, 89.
American Academy of Medicine, 573.
American Anthropometric Society, 265.
American Electro-Therapeutic Association, 174.
American Medical Association, forty-second annual meeting, 540, 572, 577, 605, 633, 661.
American Medical Temperance Society, 515, 573.
American Nurses' Association, 175.
Ammonium hydrochlorate by inhalation in membranous croup, 427.
Amniotic fluid, origin of the, 12.
Amphitheatre operations, 151.
Amyl nitrite in chloroform poisoning, 399, 483.
Anæmia, iron in, 657; following post-partum hemorrhage, treated by intra-venous saline injection, 703; pathology, symptoms, and treatment of, 150; pernicious, in a young child, 410; syphilitic, 211.
Anastomosis, intestinal, for fistula, 652; intestinal, new technique for, 725.
Anatomical material, distribution of, 237.
Anatomy, expert evidence on, 461.
Anchylosis of the jaw, spring speculum for, 299.
Anderson, R. Harcourt, some of the dangers to which epileptics are exposed, 722.
Aneurism of the arch of the aorta, tracheal tugging as a pathognomonic sign of, 406; of the first two portions of the subclavian, operative surgical treatment for, 305, 325; of the ophthalmic artery, ligature of the carotid for, 78.
Angina pectoris, discussion on, 299, 412; prognosis of, 469.
Angio-lipoma of the face, 62.
Aniline dyes in inoperable cancer, 52, 240, 301, 358, 404, 473.
Aniline oil, injections of, in tuberculosis, 269.
Ankle, primary dislocation at the, 653.
Anodal diffusion as a therapeutic agent, 133; surgery by aid of, 358.
Anthrax, recovery following excision of, 597.
Anthropology among village people, 432.
Anthropometric Society, American, first autopsy of the, 575.
Antifebrin in hard and soft chancre, 371; small and frequently repeated doses of, in the treatment of high temperature in typhoid fever and phthisis, 428.
Antipyretics, 647.
Antipyrine, 195; in chorea, 289.
Antiseptic, a new, 603.
Antiseptic dressings used at Billroth's clinic, 484.
Antiseptics, chromatic, 52; in rhyme, 516.
Anti-smoking law of New York State, 239.
Ants, surgical use for, 124.
Aorta, aneurism of the arch of the, tracheal tugging as a pathognomonic sign of, 406; hysterical, 455.
Apomorphine as an antidote in poisoning by strychnine, 79.
Apoplexy, chronic sequences of an attack of, 177; ingravescent, 213.
Appendicitis, abscesses from rupture or ulceration of the gall-bladder simulating, 327; and pericæcal inflammation, 546; death in forty-two hours, 166; in the female, 347; medical treatment of, 330; pathology of, 179.
Appendix, vermiform, removal of, 357.
Aristol, therapeutic uses of, 605, 642.
Arkansas, medical legislation in, 603.
Arms, damage to the, at birth, 681.
Army medical appointments, examination for, 212.
Army medical life, reminiscences of, 169.
Army news, 34, 67, 92, 122, 152, 191, 219, 247, 301, 332, 387, 415, 436, 471, 499, 528, 555, 611, 640, 667, 695, 724.
Arrow-poison, African, 248.
Arsenic as a domestic poison, 577; brown pigmentation form, 262; do lobsters contain, 710; domestic poisoning by, 599; in wall-papers and clothing, 487.
Arterialization, defective, oxygen in, 78.
Artery forceps, a new, 498.
Arthritis, rheumatic and rheumatoid, 139.
Arthrogryposis, 276.
Ashmead, Albert S., racial immunity and inoculation, 67; scarlet fever and the immunity of the Japanese, 527; scarlet fever in Japan, 358.
Association of American Anatomists, 247.
Astasia-abasia, 261; in Graves's disease, 429.
Asthenopia, causes of, 179.
Asthma, a neurosis, 490; euphobia pilulifora in spasmodic, 578.
Athletics among women, 112.
Atomic weights, new table of, 248.
Atrophy, acute progressive muscular, 708.
Atropine, hypnotic action of, 683.
Aulde, John, aloes—a correction, 666; studies in therapeutics—antipyrin, 195.
Austin J. Edward, strangulated cæcal hernia, extra peritoneal—herniotomy, necessitating abdominal section—complicated by mitral and aortic insufficiency—recovery, 622.
Auvard's couvert, 720.
Azoospermia, 270.

B

Babcock, J. L., a case of primary dislocation at the ankle, 653.
Bacillary partnerships, 248.
Bacilli in the Talmud, 164.
Bacteria, literature of, 192; reproduction of, 275.
Bailey, E. P., death of, 658.
Bailey, W. W., ligature of the carotid artery for aneurism of the ophthalmic, 78.
Baillarger, Jules G. F., death of, 212.
Baird, George, shot by another physician, 321.
Baker, Charles H., a case of spurious membrana tympani, 623.
Balanitis, treatment of, 336.
Baldness, prevention of, 444.
Balfour, T. S., death of, 212.
Balneo-therapeutics and mechano-therapeutics in the treatment of chronic heart disease, 198.
Banister, J. M., two interesting eye cases, 478.
Barker, Fordyce, obituary of, 660; resolutions on the death of, 688, 712.
Barry, John H., two cases of trichinosis, 677.
Bassorin paste, 292.
Baths, public, 266, 494, 628.
Beattie, Matthew, the treatment of herpes zoster, 11.
Beauty as a means of health, 431
Belladonna in labor, 681.
Bellamy, Edward, death of, 151.
Ber-beri and rice, 388.
Berlin, a private polyclinic in, 630; letters from, 328. See inoculation experiments for tuberculosis in Berlin.
Bile, elimination of iron in the, 682; persistent reflux of, into the stomach, 274.
Bill, an old surgical, 218, 295.
Biological study and anti-vivisectionists in England, 687.
Black death in England, 27.
Bladder, bone in the, 120; calculi in dermoid of the, 36; hemorrhage of the, in pregnancy, 309; prominent muscular fibres in the, mistaken for calculus, 681; spontaneous access of bacteria to, and slight vesical incompetence, as causes of cystitis, especially in the female, 585; suture of the, 325.
Bleyer, J. Mount, the phonograph and the micro-graphophone as an assistant to medical and other sciences, 697.
Blood, amount of sugar in the, in disease, 13; differential diagnosis of diseases of the, 317; effect of certain substances on

the red corpuscles, 83; germicidal action of the, 218, 490, 693; living, action of, on bacteria, 14; of the insane, 317; physical and chemical changes in the, in disease, 168; practical aspects of coagulation of, 638; the, in pneumonia, 524; uric acid in the, 82.
Bodenhamer, William, reflections and observations upon the formation, structure, function, and pathology of fistulous tracks or sinuses, especially those which constitute anal and rectal fistulæ, and the tendency of such to spontaneous obliteration and cure, 254.
Body-snatching in West Virginia, 461.
Boils, abortion of, 456; treatment of, 625.
Bolling, W. H., death of, 538.
Bone, transplantation of, 221, 237.
Book Notices:
Account of the life and works of Maister Peter Lowe, the founder of the Faculty of Physicians and Surgeons, Glasgow, by James Finlayson, M.D., 324.
Advances in bacteriology, by R. Koch, M.D., 324.
Affections of the stomach and diseases of the male genital organs, by Dr. Alexander Peyer, 242.

Transactions of the Medical Society of the State of Pennsylvania at its fortieth annual session, 242.
Transactions of the Mississippi State Medical Association for 1889, 464.
Treatise on the diseases of infancy and childhood, by J. Lewis Smith, M.D., 323.
Treatment of consumption by Koch's method, by E. A. Bridger, 464.
Treatment of epilepsy, by Dr. Ch. Féré, 324.
Treatment of ingrowing toe-nail, by Joseph Amiard, M.D., 28.
Treatment of syphilis of the nervous system, by Julius Althaus, M.D., 735.
Treatment of uterine affections by massage, by Dr. Eugene Arendt, 242.
Unsoundness of mind in its legal and medical considerations, by J. W. Hume Williams, 604.
Urinary disorders connected with the bladder, prostate, and urethra, by Reginald Harrison, F.R.C.S., 323.
Urine in neurotic disorders, by Dr. Alexander Peyer, 147.
Wood's medical and surgical monographs, 28, 145, 147, 242, 324, 464, 604, 736.
Workhouse and its medical officer, by Dr. Alfred Sheen, 324.
Boracic acid in constipation, 115; in tuberculosis, 116.
Borelli, Giambatista, death of, 212.
Bosnia, woman's hospital in, 713.
Bosworth, F. H., on certain hygienic measures in the treatment of catarrhal affections of the upper air-passages, 394.
Bradshaw lecture at the College of Surgeons, 65.
Brain, and spinal cord, relation of concussion of, to inflammatory and other morbid changes in these organs, 605; hemorrhage into the, 440; of Laura Bridgman, 627; operation for tumor of the centrum ovale, 178; pistol-shot wound of the, 61; some of the remote effects of injury to, in delivery, 577.
Braun, Carl Rudolph, death of, 517.
Breath, bad, 121.
Breech presentation, forceps in, 203.
Bridgman, Laura, the brain of, 627.
Briggs, Charles G., dislocation of the head of the ulna forward, without a fracture of the radius, 553.
Bright's disease, insanity as a symptom of, 428; of pregnancy, 1.
Bromide, ferric, 485.
Bromides, are they harmless? 719.
Bromidrosis of the feet, application for, 513.
Bronchial lymph nodes, hemorrhage into and around, 166; primary infection of tuberculosis in, in children, 186; tuberculosis limited to the, 270.
Bronchus, death from a cork in the, 539.
Brown-Séquard's fluid in tuberculosis, 144.
Brush, Arthur C., acute case of progressive muscular atrophy, 708.
Bryant, Joseph D., the operative surgical treatment for aneurism of the first two portions of the subclavian, 305, 325.
Bryce, P., care of the private insane, 33.
Bryonia, 574.
Bulkley, L. Duncan, on the causes of eczema, 395.
Bull, William T., on three cases of pylorectomy with gastro-enterostomy, 39.
Bunts, F. E., shock, 509.
Butter, the acid of, 321.
Byers, J. Wellington, the germicidal action of the blood, 218, 693.
Byford, Henry T., a third series of peritoneal sections, comparative study of one hundred and fifty-nine consecutive cases, 533.

C

Cabinet officer of public health, 685, 723.
Cady, George P., death of, 688.
Cæsarean section, 663; a primitive, 556; modern methods of performing, 470; post-mortem, 513.
Caffeine, hypodermic injections of, in post-partum hemorrhage, 13.
Calculus, biliary, 63; biliary, cholecystotomy for, 298; in dermoid growths of the bladder, 36; salivary, 117; vesical, prominent muscular fibres mistaken for, 681; vesical, some sources of error in sounding for, 111.
California, and old age, 170; Indians, diseases of, 104; medical legislation in, 240, 491.
Calomel habit, 513.
Calomel in the treatment of pneumonia, 653.
Camp, Nathan, death of, 379.
Camphoric acid and tellurate of sodium as antihidrotics, 568.
Camthey, Horace, Koch's lymph in Florida, 654.
Cancer, and pork-eating, 246; caustic treatment of, 269; micro-organism in, 20, 429; new "cures" for, 515; of the breast, causes of, 211; of the cervix uteri with co-existing pregnancy—vaginal hysterectomy recovery, 259; of the pylorus, operations for, 37, 39, 62; of the rectum, extirpation of, in two sitf tings, 206; of the stomach, the gastric functions in, 288; of the uterus, salol as a disinfectant in, 525; psorosperms in, 303; primary, of the lungs, 438; pyoktanin for, 52, 240, 301, 358, 404, 473.
Candy, alcohol in, 576.
Cannabis indica in colic of horses, 539.
Cannibalism, medical, 170, 331.
Cantharidate of potassium in tuberculosis, 293.
Cantharidin in pulmonary phthisis, 596.
Carbuncle, treatment of, 556.
Carotid artery, ligature of the, for aneurism of the ophthalmic, 78.
Cataract, use of platinum instruments in the extraction of, 179.
Catarrh, cure of, 181; naso-pharyngeal and gastric, mutual relations of, 674; of the upper air-passages, hygienic measures in the treatment of, 394.
Catheters, rubber, sterilization of, 403.
Cause of diphtheria in rural districts, 730.
Cautery, Paquelin, how to keep in good order, 248.
Cell, animal, chemistry of the, 544.
Centrum ovale, operation for tumor of the, 178.
Cerebellar hemorrhage with complete paralysis on the same side as the lesion, 118.
Cerebral injuries, sensory derangements following, 419.
Chamberlain, F. T., a case of cold abscess of the epiglottis, of probably four years duration, 427.
Chancre, antifebrin in, 371; excision of, in the preventive treatment of syphilis, 686; multiple, 560; of the fingers, 69; soft, grattage in the treatment of, 568.
Charities of New York City, 236; of New York State, 212.
Charity, medical, how ambitious doctors abuse, 694.
Cheap doctors, 693.
Cheesman, W. S., elbow-splint and shoulder-cap, combined, 10.
Chemiotaxis, a property of phagocytes, 485.
Chestnut leaves for ivy-poisoning, 35.
Chicago, a German medical college in, 518; a new medical society in, 360; Academy of Medicine in, 220.
Chichester, W. R., treatment of balanitis, 356.
Child, acquired syphilis in a young, 158; fracture of the neck of the femur in a, 165; pernicious anæmia in a young, 410; usually high temperature in a, 553; viable, born at six and a half months, 720.
Childbirth, daily discharge of watery fluid after, 664; damage to the arms at, 681.
Children, albuminuria in, 137; brains of feeble-minded, 403; cervical adenitis in, 148; diabetes mellitus in, 289; diagnosis of pulmonary cavities in, 234; hepatic cirrhosis in, 624; indican in the urine of, 233; Koch treatment of tuberculosis in, 59; malaria in, 383; nocturnal incontinence of, posture in the treatment of, 110; some points in the dietetic management of, 373; time of day when they are born, 704; tuberculosis in, 186; unfavorable action of Koch's method in the treatment of tuberculosis in, 500; young, stomach washing in, 205.
China, a medical college in the interior of, 350; prevailing fevers in, 668.
Chloasma in a hypospadiac, 564.
Chloral habitués, a home for, 658.
Chloralamid, how to give, 93.
Chloroform, amyl nitrite as an antidote to, 399, 483; and ether, deaths from, 606; danger of administering, near an open flame, 384; in tracheotomy, 318; narcosis, mortality from, 626.
Chlorosis, new theory of the pathology of, 176; treatment of, 286.
Cholecystotomy for biliary calculi, 298.
Cholera, Asiatic, in a dog, 388; discoverer of the bacillus of, 612; in Japan from 1884 to 1887, 276; in Syria, 210; in the Russian North Pacific, 295; sudden outbreak of, 302; vagus treatment of, 20.
Chorea, antipyrin in, 289; epidemic, 318; laryngeal, 526.
Choroid, double rupture of, below the optic papilla, 480; melanotic sarcoma of the, 478.
Churchill, Frank, hystero-neurosis and melancholia cured by trachelorrhaphy, 135.
Chyle, flow of, from the skin and kidneys, 488.
Chylothorax, 318.
Cigarette smoking, 655.
Cinchonidine sulphate in intermittent fever, 246.
Circumcision, cocaine in, 403; congenital, 21; painless, 78.
Cirrhosis, hepatic, in children, 624.

Cities, large, micro-organisms in, 191.
Cleaves, Margaret A., vesical hemorrhage in pregnancy, with report of a case, 309.
Cleveland, Clement, perineorrhaphy; a plea for immediate repair, with the description of a new method of suturing, 193, 213.
Climacteric period, heart disorders of women at the, 111.
Clinic, a private, in Berlin, 630; International, in Paris, 239; the Transfiguration, 66.
Cocaine by anodal diffusion, 358; habitués, a home for, 658; in circumcision, 403; in dental surgery, 526; in small-pox, 500; use of, in gynecological surgery, 663.
Cocoanut-water as a culture-fluid, 205.
Coddling, 667.
Cod-liver oil, inunctions of, 192; scarcity of, 434.
Coe, H. C., a case of chronic abscess of the abdominal wall, simulating malignant intra-peritoneal tumor, 132.
Cœliotomy for rupture of the parturient uterus, 663.
Coffee, action of, in bacteria, 360.
Coit, Henry L., an instrument for treating enlarged tonsils by electrolysis, 470.
Coles, Abraham, death of, 539.
College of Physicians and Surgeons, new departure of the, 208.
Collins, Joseph, a case of enteric fever with peculiarities, 356.
Comma-bacillus, discoverer of, 612.
Condurango and condurangin, 625.
Conjunctiva, hemorrhage from the, following the application of Credé's method in a new-born infant, 456.
Connecticut State Medical Society, centennial of the, 175.
Consanguineous marriages, a study of, 538.
Constantinople, opening of a large hospital in, 491.
Constipation, habitual, treatment of 82, 522; new remedy for, 115; voluntary, 556.
Contagious diseases, and funerals, 263; in New York City, weekly statement, 35, 68, 92, 123, 152, 191, 220, 247, 302, 332, 360, 388, 415, 444, 471, 499, 528, 555, 612, 667, 696, 724; in public and private schools, 292.
Cook, Avery, death of, 435.
Cord, trephining the, 234.
Cornell, Stanley S., the frequent localization of circumscribed pleuritis beneath the scapulæ, 417.
Corns, salicylic acid for, 49.
Coroner system in New York, 656; the, and the lymph, 172.
Coroner's juries, the value of, 535.
Coryza, treatment of, 436.
Cough, barking, of puberty, 138; its uses, significance, and indications, 336, 355.
Courtney, J. Elvin, case of traumatic epilepsy, 370.
Couvert, Auvard's, 720.
Cowdrey, Stevens G., death of, 265.
Cramps in the legs, viburnum for, 421.
Craniectomy for microcephalus, 232.
Craniotomy, linear, for defective mental development, 607.
Crater, Edward W., death of, 436.
Credé's method, conjunctival hemorrhage following the application of, in a new-born infant, 456.
Cremation, a British view on, 284.
Creolin, eczema from the use of, 49; in erysipelas and eczema, 235.
Crothers, T. D., institutions for drunkards, 245.
Croup, membranous, hydrochlorate of ammonium by inhalation in, 427.
Culture-fluid, cocoanut-water as a, 205.
Cure, an evidence of, 68.
Cures, modern discoveries of new, 537.
Curve of health, 291.
Cutter, George R., resolutions on the death of, 322.
Cystinuria, 371.
Cystitis in diabetes, 82; some causes of, in the female, 585.
Cystoscope, demonstration of a new, 384.
Cystoscopy, art of, and its uses, 209; progress of, in the last three years, 178.
Cystotomy, supra-pubic, 607; supra-pubic, how Lawson Tait does a, 610.

D

Da Costa, Dr., resignation of, from the Jefferson Medical College, 518.
Dale, W. W., death of, 295.
Damage cases, physical examination in, 380.
Dana, Charles L., the reality of rabies, 3.
Dandruff, cure of, 556.
Davis, William B., albuminuria in persons apparently healthy, and a consideration of its relation to life-insurance, 669.
Dawbarn, Robert H. M., a vegetable plate, also a new technique in intestinal anastomosis, 725; surgery by aid of anodal diffusion, 358.
Dead bodies, new process of preserving, 20.
Death, after a minor operation, 721; sudden, 265.
Deciduous man, a, 212.
Delirium, acute, hyperalimentation in, 136.
Dental practice, regulation of, in Connecticut, 175.
Dental surgery, cocaine in, 526.
Dentistry and syphilis, 570.
Derby, Richard H., successful effort to restore binocular vision by a partial tenotomy of the superior rectus, 567.
Dermatitis gangrenosa infantum, 562.
Dermatological practice, some unusual cases from, 559.
Dermatological uses, a new base for, 292.
Dermatologist, compensation for the, 17.
Dermoid cyst, 272; of the bladder, calculi in, 36.
Dessau, S. Henry, observations on rational therapeutics, 557.
Dewey, Richard, amphitheatre operations, 151.
Dexter, Ransom, death of, 434.
Diabetes, cystitis in, 82; mellitus, 481, 581; mellitus in children, 289; some chemical points in the treatment of, 496; three kinds of, 289.
Diarrhœa, chronic tropical, treatment of, 499.
Digestion in the small intestine, 626; the free acid of the gastric juice during, 83.
Diller, Theodore, a case of idiopathic spinal hemorrhage, 651.
Diphtheria, a protective against, 19; cause of death in, 514; etiology of, 445; hot dilute sulphurous acid in the treatment of, 402; methyl-blue in, 356; micro-organism in, 484; pathology of, 376; permanganate of potassium in, 682; pharyngeal, submucous injections in, 662; production of immunity from, 84, prophylaxis and treatment of, 136, 258, 661; recent contributions to the knowledge of, 577; submembranous medication in the treatment of, 219; sulphate of zinc in, 527; transmission of, from animals to man, 388; zinc sulphate in, 402.
Disease, a new, in Africa, 683.
Diseases, named for doctors, 290; prevailing in different countries, 555.
Disinfection, hints on, 524.
Dislocation, primary, at the ankle, 653.
Dispensary physician, responsibility of a, 459; question, the, 386, 470; the midwifery, 632.
Diuretin, 35.
Divulsion of urethral stricture, a new instrument for, 646.
Doctor, the village, 114
Doctors, and advertising, 192; cheap, 571.
Dodd, William S., pork-eating and cancer, 246.
D'Oench, F. E., a case of traumatic paralysis of the abducent and oculo-motor nerves, 402.
Domestic animals, studying disease in, 520.
Douches, alternating cold and hot, in the induction of premature labor, 682.
Drainage, in surgery, use and abuse of, 315; siphon, in empyema, 234; supra-pubic, 297.
Drainage-tubes, quill, 191, 248.
Drew, C., intestinal anastomosis in a youthful case of fecal fistula resulting from hernia, 652.
Drug eruptions, causes of, 288.
Drugs, impure, 138; regulating the price of, 556.
Drunkards, institutions for, 173, 245, 331.
Dubois, Coert, obituary of, 60.
Duboisine, hypnotic action of, 683.
Duncan, Mathews, honor to the memory of, 265.
Duodenum, ulcer of the, 496.
Dupon, F. S., permanganate of potassium as an application to the bites of poisonous insects, 36.
Durand, C. Ferdinand, swelling of the feet in warm weather, 554.
Duvall, Marius, death of, 265.
Dwelling-house in relation to tuberculosis, 667.
Dysentery, sulphate of magnesium in, 683.
Dysmenorrhœa, membranous, 120.
Dyspepsia, acid, 355.

E

Ear, chronic purulent disease of the middle, 465; disease, study of, in Vienna, 244; hook for the removal of foreign bodies from the, 528; improvement of hearing after removing the ossicles, 466; removal of foreign bodies from the, resulting in the cure of aural hallucinations, 680; traumatic occlusion of the external auditory meatus, 526.
Earache, treatment of, 428.
Eaton, F. B., fracture of base of skull, causing total paralysis of both sixth cranial nerves and partial paralysis of the sensory root of both fifth cranial nerves. Tenotomy—advancement of Tenon's capsule, 617.
Eczema, causes of, 395; creolin in, 235; from the use of creolin, 49.
Edebohls, George M., a self-retaining vaginal speculum for operations in the dorsal position, 283.
Edson, Cyrus, some questions about issues and setons, 457.
Education, medical, 236.
Eichberg, Joseph, a case of acute ascending paralysis—rapidly fatal issue, 226.
Einhorn, Max, a new method for direct electrization of the stomach, 529; Koch's method of treatment for tuberculosis, from personal observations in Berlin, 47; methyl-blue in malignant inoperable growths, 358.
Elbow splint and shoulder-cap combined, 10.
Electricity, adaptation of the Edison current to general office use, 720; anodal diffusion as a therapeutic agent, 133; as a therapeutic agent, 579; in incontinence of urine, 683; in the treatment of lupus, 426; in the treatment of menorrhagia and metrorrhagia, 216, 366; induced currents of, physiological and therapeutical properties of, 187, 201; static, new system of therapeutic administration of, 97; use of, in gynecology, 215.
Electrization of the stomach, influence of direct, upon gastric secretion, 677; of the stomach, new method for direct, 529.
Electro-cautery in surgery, with special reference to its use in the nose, mouth, and throat, 178.
Electrodes for use in rhinology and laryngology, 118.
Electrolysis in uterine fibroids, 635; instrument for treating enlarged tonsils by, 470; linear, in the treatment of stricture, 14; platinum needles for, 607.
Electro puncture in chronic hydrocele, 235.
Elliot, George T., some unusual cases from dermatological practice, 559.
Ellis, R., sexual education for the young, 497.
Ellis, R. C., nothing new under the sun, 527.
Embalming, proposed law on, 181; regulation of, 240.

Embryotomy of the living fœtus, is it justifiable? 641, 689.
Emmenagogue, indigo as an, 581.
Emphysema following rupture of the Eustachian tube, 524
Empyema, pathology of, 139; siphon drainage in, 234.
Endocarditis, tubercular, 207.
Endometritis, chronic, 580; chronic, is it dangerous to make local applications in, 274.
Endothelioma of the pleura, 271.
Enzymes, the, and Koch's discovery, 50.
Epididymis, cysts of, 288.
Epiglottis, cold abscess of the, 427.
Epilepsy, indications for trephining in, 31; Jacksonian, surgical treatment of, 178; traumatic, 370; traumatic, trephining for, 297.
Epileptic insanity, 719.
Epileptics, proposed colony for, 304; some of the dangers to which they are exposed, 722.
Epistaxis, McDowell's method of controlling, 81.
Epler, E. G., foreign body in the lung, 729.
Eruptions, drug, causes of, 288.
Erysipelas, creolin in, 235.
Erythema, relapsing desquamative, 563.
Ether, and chloroform, deaths from, 606; death following the administration of, 721; drinking in Michigan, 630; paralysis following hypodermic injection of, 266.
Eucalyptus drainage and malarial fever, 13.
Euphorbia pilulifera in spasmodic asthma, 578.
Euphorine, 137.
Eustachian tube, emphysema following rupture of the, 524.
Evans, Thomas R., is the contagion of typhus always imported? 639; was it enteric fever? 443.
Exophthalmic goitre, novel surgical treatment of, 174.
Exostoses, multiple cancellous, 439.
Expert evidence in anatomy, 461; suit for fees, 322.
Extra-uterine pregnancy, 629, 662.
Eye, diseases of the, hospital for contagious, 462; diseases of, hypodermic medication in, 107; optic neuritis following influenza, 683; strain, headache from, 179; traumatic paralysis of the abducent and oculo-motor nerves, 402.

F

Face presentations, posterior, treatment of, 664.
Families, opposition to large, 359.
Family, a large, 472.
Faradization, bipolar, 187, 201; for enuresis, 683.
Fat men's congress at Berlin, 53.
Father Mollinger's faith-cure, 730.
Faucial and pharyngeal tenesmus, 204.
Fears, morbid, and allied disorders, 404.
Fees, cutting down, 17, 19; for medical study in England and the United States, 517, 686; legislation to reduce, 323; medical, State regulation of, 265.
Feet, application for bromidrosis of the, 513; excessive sweating of the, zinc chloride for, 644; swelling of the, in warm weather, 554.
Fellowships, medical, in Harvard, 687.
Femur, differential diagnosis of dislocation and fracture of the neck of the, 302; fracture of the neck of the, in a child, 165; separation of the condyloid epiphysis of the, 11.
Fever in New York, four types of, 382.
Fevers, infectious, unity of, 239.
Fibroid tumors of the uterus, electrical treatment of, 635; operations for, 288.
Fibro-myoma, a large, 440.
Filth disease, what constitutes a, 624.
Fingers, chancres of the, 69.
Fischer, Louis, naso-pharyngeal catarrh a causative factor in gastric catarrh, 674; submembranous medication in the treatment of diphtheria, 219.
Fisher, William R., an epidemic of pneumonia and the calomel treatment of the disease, 653.
Fistulous tracks or sinuses, formation, structure, function and pathology of, 254.
Flat-foot, 137; painful, osteotomy for, 124.
Fœtus, living, is embryotomy of, justifiable? 641, 689; size of the, 122.
Food, curious, 124.
Foot-and-mouth disease, pyoktanin in, 683.
Forceps, a new artery, 498; anticraniotomy, advantages of, over version in pelvic deformities, 717; obstetrical, cases in which it is needed, 634; obstetrical, engagement of the child's arm in the fenestrum of the, 635; obstetrical, use of, in breech cases, 203.
Foreign bodies, in the bronchus, 539; in the ear, cure of aural hallucinations by removal of, 680; in the larynx, 709; in the lung, 729; in the nose, 729; in the nose, pneumatic method of removing, 93; in the stomach, "potato cure" for, 11, 218.
Forest, W. E., the relief of pelvic and abdominal pain by hot colon douches, 592.
Fracture, exploratory incision in cases of, when doubt exists as to their character, 607; massage in, 234; of the femur in children, perpendicular extension in the treatment of, 218; of the leg, non-operative treatment of delayed union in, 130.
France, dwindling population of, 320; dwindling population of, another explanation of, 651; dwindling population of, legislation respecting, 684; medical law in, 538.
Franklinic interrupted current, 97.
Fredericks, L. A., can the tubercle bacillus be destroyed by the pneumococcus? 695.
Freeman, Alpheus, the dispensary abuse, 470.
Fremitus, vocal, diagnostic value of, in pneumonia, 643, 723.
French, Gervis, death of, 713.
French Surgical Congress, 492, 603.
Friedreich's disease, treatment of, 629.
Funerals and contagious diseases, 263.
Funis, separation of from the child during parturition, 167.
Furuncle, how to abort a, 456; treatment of, 242.

G

Gall-bladder, abscesses simulating appendicitis from rupture or ulceration of the, 327.
Gall-stones, 63; frequency of perforation and peritonitis from, in old persons, 327; frequent, and hepatic colic rare, 214; sweet oil in the treatment of, 16, 693.
Gangrene, of the skin in an infant, 426; slow, 495.
Garrish, John P., death of, 435.
Gary, Thomas P. death of, 713.
Gastric juice, the free acid of, during digestion, 83.
Gastritis and pharyngitis, mutual relations of, 674.
Gastro-enterostomy rather than resection for cancer of the pylorus, 37, 62.
Gastrostomy, Hahn's method of performing, 373.
Gastrotomy, 178.
Genital organs, relation of affections of the male, to stomach disorders, 484.
Genito-urinary tract, primary tuberculosis of the, 119.
German Congress of Internal Medicine, 602, 632; Surgical Congress, 519.
Germicidal power of the blood, 218, 490, 693.
Gestation, ectopic, 629, 662.
Gleitzmann, J. W., experience with trichloracetic acid in two hundred cases of affections of the throat and nose, with demonstration of instruments, 312.
Gluck, Isidor, the treatment of an acute attack of hay fever, 564.
Glucose and iodine, advantages of combining, 679.
Goelet, Augustin H., the treatment of menorrhagia and metrorrhagia by the chemical galvano-caustic action of the positive pole, 366.
Goitre, exophthalmic, novel surgical treatment of, 174.
Gold and manganese, subcutaneous administration of, in the treatment of tuberculosis, 338, 354.
Gonococcus, medico-legal value of the, 234; recognition of, 317.
Gonorrhœa, acute anterior, 161; treatment of, 716.
Gonorrhœal salpingitis, 234.
Gordon, Bernard, two cases of imaginary poisoning, 654.
Graefe, Dr., the latest from Berlin, 59.
Grandin, Egbert H., is embryotomy of the living fœtus justifiable? 641, 689.
Graves's disease, astasia-abasia in, 429.
Gray, Landon Carter, hydrophobia, its clinical aspect, 6.
Griffin, Henry A., a case of hemorrhage into and around the bronchial glands, 166.
Grip, the. *See* Influenza.
Gulliver, George, death of, 212.
Gum arabic, scarcity of, 556.
Gundry, Richard, death of, 518.
Gynecologists of New York, a blessing upon, 668.
Gynecology, Chinese, 528; use of cocaine in, 663; use of electricity in, 215.

H

Hæmaturia with brief cerebral symptoms, 215.
Hæmoglobinuria and quinine, 388.
Hæmolymph glands, 416.
Hæmoptysis in apparently healthy persons, 167.
Hall, A. L., sensory derangements following intra-cerebral injuries, 419.
Hallucinations, cure of aural, by removal of foreign bodies from the ear, 680.
Hamilton, William D., stormy convalescence after removal of intra-abdominal tumors, 550.
Hammond, Græme M., astasia and abasia, with the presentation of a case, 261.
Harelip, new operation for, 547.
Hartnack, Edmund, death of, 294, 351.
Hartwig, Marcell, essential hydrops, 80.
Harvard medical fellowships at, 687; Medical Society of New York City, 265.
Haskell, C. N., the diagnostic value of vocal fremitus in pneumonia, 723.
Haslam, George, notes on acid dyspepsia, 355.
Hat, a medical, 294.
Havana, a Society of Hygiene in, 686.
Hawking, treatment of, 380.
Hay fever, treatment of an acute attack of, 564.
Hayne, Marcus S., death of, 460.
Hazen, Edward, death of, 240.
Headache from defective intra-tympanic aëration, 438; ocular, 179; classification of, 568.
Healey, James C., death of, 434.
Health, beauty as a means of, 431; State Board of, 52; the curve of, 291.
Health-officer in the cabinet, 685, 723; verdict against a, 379.
Heart, a visible, 207; disease of, chronic, balneo-therapeutics and mechano-therapeutics in the treatment of, 198; disease of, consequent on malarial fevers, 111; disease of, prognosis in, 468; disease of, with pulmonary œdema, relieved by oxygen inhalation, 483; disorders of, in climacteric women, 111; palpitation of, cold applications for the relief of, 204; rupture of the right ventricle, 621; structural diseases of the, considered from the point of view of prognosis, 412, 442; valvular disease of the, changes in the myocardium in, 254.
Hebrews in the United States, vital statistics of the, 171.

Hemianopsia, 389.
Hemorrhage into and around the bronchial glands, 166; post-partum, hypodermic injections of caffeine in, 13.
Henry, J. T., the calomel habit, 513.
Hernia, new method for the relief of, 84*a*; radical treatment of, 235, 547; strangulated extra-peritoneal cæcal, 622; strangulated, treatment of, when the intestine is gangrenous or ulcerated, 442; treatment of, with the hank truss, 616, 636.
Herpes zoster, treatment of, 11, 426.
Heteradelphia, a case of, 658.
Heteratopia of the spinal cord, 497.
Hip, disease of the, early resection or conservative treatment of, 606; first successful amputation at the, in America, 712; excision of the, 93; old traumatic dislocation of, new operation for, 320.
Hitchcock, Hiram H., death of, 461.
Hogeboom, Charles L., oil of peppermint in the treatment of grip, 483.
Holden, Edgar, an old story about a new syringe, 245.
Holt, A. F., death of, 19.
Holt, L. Emmett, cerebro-spinal meningitis in an infant due to the diplococcus pneumoniæ of Fraenkel and Weichselbaum, 43, 64.
Homœopathy in Russia, 144.
Hooper, Franklin H., a case of tumor of the larynx, showing amyloid degeneration, 285.
Hospital Graduates' Club, anniversary dinner of the, 658; internes and hysteria, 571; Sunday Association, the saloons and the, 140; superintendents, should they be physicians? 684, 711; system, private, 172.
Hospitals, compulsory treatment in, 152; large, disadvantages of, 115; superfluity of, 349.
Hot colon douches for the relief of pelvic and abdominal pain, 592; water as a remedial agent, 554.
Houston, D. W., urinalysis for sugar, qualitative and quantitative, 457.
Howe, John R., death of, 294.
Hubbard, Dwight L., hydrochlorate of ammonium by inhalation in membranous croup, 427.
Hubbard, George E., cheap doctors, 683.
Hunger and infection, 556.
Hunt, Sylvester H., death of, 538.
Hunterian Oration at the College of Surgeons, 329.
Huxley on the aim of life, 686.
Hydatid of the lung, 65.
Hydrocele, chronic, electro-puncture in, 235; treatment of, by carbolic acid *versus* the radical operation, 715.
Hydrocephalus, chronic external, 441.
Hydrogen peroxide, preservation of, 569.
Hydrophobia, a case of, 521; deaths from, 276; discussion on, 29; paralytic, suffered death from, 265; the clinical aspect of, 6; the reality of, 3.
Hydrops, essential, 79, 80.
Hygiene, a Society of, in Havana, 686; of our public schools, 211.
Hymen, imperforate, 136.
Hyperidrosis of the feet, chloride of zinc for, 644.
Hypnal, the new nervine, 8.
Hypnotic action of atropine and duboisine, 683.
Hypnotics, two new, 114.
Hypnotism in public, suppression of, 380.
Hypodermic injections, an improved syringe for, 190; antiseptic syringe for, 151.
Hypodermic medication in diseases of the eye, 107.
Hysteria, a suspected case of, in a man, 326; and hospital internes, 571; in the male, 675; traumatic, 179.
Hystero-neurosis and melancholia cured by trachelorrhaphy, 135.

I

Ice-cradle to reduce temperature, 294.
Ice-cream poisoning, 713.
Ichthyol, to mask the odor of, 444.
Idiocy, the professions and, 113.
Ileo-cæcal value, Pean's treatment of stricture of, 287.
Imber, Naphtali Herz, bacilli in the Talmud, 164.
Immigration and disease, 433, 434, 657.
Immunity, and phagocytosis, 485; racial, and inoculation, 67, 246.
Incontinence of urine, faradization in, 683; nocturnal, in children, posture in the treatment of, 110.
Incubator, Auvard's, 720.
Indians, medical attendance on the, 378; Northern California, diseases of, 104.
Indican in the urine of children, 233.
Indigo as an emmenagogue, 581.
Inebriates, State care of, 378.
Inebriety, narcotic, prevention of, 266.
Infant, gangrene of the skin in an, 426.
Infants, dress for, 662; insomnia in, 500.
Infarct of the placenta, white,
Infection and hunger, 556.
Influenza, among the Alaska Indians, 712; facts learned from last year's epidemic of, 374; immunity against, furnished by vaccination, 584; in Austria, 595; in Chicago, 519; in Japan, 264; in Russia, studies on the, 531; names of the, 459; pandemics of, 430; retro-ocular neuritis following, 683; treatment of, 444, 463, 483.
Ingrowing toe-nail, treatment of, 151.
Inhalation of tobacco smoke, 655.
Inoculation experiments in tuberculosis with Koch's lymph, 73, 578, 589; a large dose of tuberculin, 295; complications and dangers of, 44; delayed reaction from lymph, 143; direct application of the lymph to pulmonary cavities, 351; effects of, upon the sputum, 143; further contributions to the pathology of the lymph, 267; government control of the manufacture of parataloid, 211; in Chicago, 350; in Cincinnati, 321; in Berlin, 27, 47, 59, 293, 328; in Florida, 654; in London, 120, 188, 238, 243, 549, 609, 664; in New York, 21, 55, 86, 116, 249, 277, 282, 440, 450, 493, 690; in Spain, 322; in surgical tuberculosis, 211; in Vienna, 66, 244; official regulations concerning the sale of the lymph, 351; official report on, 405; pathological changes resulting from, 209; peptonuria after, 84*b*; progress of, abroad, 51; sale of the lymph in Berlin, 435; success of treatment dependent possibly on relation between the amount of tuberculous tissue and dose of lymph, 192; the composition of Koch's lymph, 84*d*; the lung from a case treated by Koch's lymph, 272; the lymph and its reactions, 84; value of the method, 545; varying strength of parataloid, 247, 438.
Inoculation, for lupus, death following, 21; racial immunity and, 67, 246.
Insane, blood and urine of the, 317; care of the private, 33; chronic, agricultural colonies for the, 123; commitment of the, 415; of New York State, 275; State care of the, 539; the law in relation to the, 489; voluntary patients in hospitals for the, 349.
Insane asylums, can the gynecologist aid the alienist in, 633.
Insanity, and murder, 349; as a symptom of Bright's disease, 428; definition of, 360; epileptic, 719; in criminal cases, 114; maniacal, relieved by trephining, 297; signs of, 208.
Insomnia in infants, 500.
Interdental pry, a modified, 274.
Intermittent fever, cinchonidine sulphate in, 246.
International clinique at Paris, 239.
International congress of microbes at Berlin, 68.
International Medical Congress, medal of the, 575.
Intestinal anastomosis for fistula, 652; anastomosis, new technique for, 725; atrophy, progressive, 204; obstruction, 83; surgery, use of the elastic ligature in, 546; worms, 471.
Intestine, small, digestion in the, 626.
Intra-abdominal tumors, stormy convalescence after the removal of, 550.
Intubation of the larynx, in an infant of ten weeks, 483; in Germany, 682; O'Dwyer's views on, 696.
Iodide of sodium, therapeutic value of, 470.
Iodine, and glucose, advantages of combining, 679; and the salicylates, antagonism between, as regards exudations and transudations, 206.
Iodism, prevention of, 632.
Iron, elimination of, by the bile, 682; in anæmia, 657; perbromide of, 485.
Issues and setons, 457.
Italian Hospital in New York, 53.
Ivy-poisoning, chestnut leaves for, 35.

J

Jackson, A. Wilbur, two typical cases of lupus treated with galvano-puncture, 426.
Jacobi, A., inoculations with Professor Koch's "tuberculin," 249, 277.
Jacques, Dr., death of, 378.
Japan, cholera in, from 1884 to 1887, 276; prevalence of the grip in, 264; scarlet fever in, 358; the medical profession in, 598.
Japanese, immunity from scarlet fever of the, 527.
Jaw, necrosis of, 661; recurring luxation of, 298.
Jews, vital statistics of American, 20.
Johns Hopkins Hospital, Historical Club at, 52; cost of the, 124.
Johnson, Alexander B., a case of anthrax—excision of infected tissue—recovery, 597.
Johnson, F. M., oxygen an adjuvant in defective arterialization, 78.
Johnson, Hosmer Allen, death of, 295; resolutions on the death of, 380.
Johnson, T. M., antipyretics, 647.
Johnston, W. H., is it dangerous to make local applications in chronic endometritis, 274.
Joints, expectant or operative treatment of tuberculosis of, 377.
Jones, Allen A., the influence of direct electrization upon gastric secretion, 677.
Jurisprudence, medical, notes in, 346.

K

Kakeles, M. S., a case of loose body in the knee-joint, with description of theories of origin, pathology, symptoms, and treatment of loose bodies in joints, 700.
Kammerer, F., report of three cases of nephrectomy, 368, 383.
Kaoumponli, 683.
Kava-kava, physiological action of, 403.
Kelly, J. D., hysteria in the male, 675; our mineral spring resources, 507.
Kelliher, M. W., a case of rabies, 521; a five-inch hair-pin in the posterior nares, 729.
Kentucky State Medical Society, 736.
Kerley, Charles G., severe catarrhal laryngitis, asphyxia, intubation, recovery in an infant aged ten weeks, 483.
Kerwin, M. H., death of, 322.
Ketch, Samuel, posterior rachitic curvature of the spine, 9.
Kidney, horseshoe, nephrectomy of one-half of a, 110; rupture of the, 214; scrofulous, 286; single, with acute interstitial nephritis and colloid carcinoma of the bladder, 495.
Kilmer, S. L., sulphate of zinc in diphtheria, 402.
Kingman, R. A., new uterine repositor, 34.
Kirch, G. W., the proposed Italian Hospital, 53.
Kirkendall, J. S., racial immunity and inoculation, 246.

Kissam, Philip Platt, death of, 712.
Kitchen, J. M. W., some comments on the present therapy of pulmonary consumption, 401.
Knee-joint, injury of the, 177; loose bodies in the, 700; sarcoma of the, 495.
Koch, lay comments on, 114; men who are working with, 54; relations of, to the German Government, 143.
Koch's discovery and the enzymes, 50; five original cases, 77; lymph inoculation. *See* Inoculation experiments for tuberculosis.
Kramer, S. P., Koch's lymph at the Good Samaritan Hospital in Cincinnati, 321.
Kretzschmar, Paul H., death of, 518.

L

Labor, belladonna in, 681; premature, new method of inducing, 681.
Lacing, tight, death from, 584.
Lancaster, C. C., death of, 212.
Langenbeck House, laying the corner-stone of the, 520.
Language, a pathological, 76, 245.
Laparotomy, after-treatment of cases of, 634; comparative study of one hundred and fifty-nine consecutive cases, 533; exploratory, in a case of tubercular peritonitis, 466; for rupture of the parturient uterus, 663; for tubo-ovarian disease, 678; ten selected cases of, 547.
Laryngeal chorea, 526.
Laryngitis, catarrhal, intubation for, in an infant of ten weeks, 483.
Larynx, foreign body in the, 709; removal of a large fragment of glass from, 478; tumor of, showing amyloid degeneration, 285.
Laughing-plant, 457.
Law, medical, in Alabama, 463, 491; the, and the insane, 489.
Lead-poisoning, 411, 413.
Leaming, James R., cough, its uses, significance, and indications, 336, 355.
Legislation medical, activity in, 433.
Leidy, Philip, death of, 520.
Leprosy in British Columbia, 407; in old age, 176.
Leszynsky, William M., some practical points in the diagnosis of tabes, and the significance of certain symptoms, 424.
Letter, from Berlin, 328. *See* inoculation experiments for tuberculosis in Berlin; from London, 65, 120, 150, 188, 243, 299, 329, 357, 411, 442, 468, 496, 549, 609, 638, 664; from Vienna, 217, 244.
Leucocytes, the work of, 486.
Leukæmia, pseudo-, 63.
Levis, Richard J., resolutions on the death of, 35.
Lewis, Daniel, notes on the therapeutic uses of aristol, 642.
Library, medical, New York State, 240, 433.
Life insurance, and eyesight, 535; physicians in relation to, 491; professional secresy and, 668; relation of functional albuminuria to, 669, 710.
Life, Huxley on the aim of, 686.
Ligature-box, a new, 122.
Lipoma, angio-, of the face, 62.
Liqueurs, dangers of, 174.
Literature, medical, abundance of, 50.
Litholapaxy, improvement of evacuators for, and the later developments of the operation, 361; one disadvantage of, 118.
Liver, cirrhosis of, in children, 624; malarial abscess of the, 322; surgery of the, 168, 357; treatment of abscess of the, 318.
Lobsters, do they contain arsenic? 710.
Lockwood, George Roe, purpura hæmorrhagica, 155.
Locomotor ataxia, points in the diagnosis of, 428.
Logan, Joseph P., death of, 659.
London, letter from, 65, 120, 150, 188, 243, 299, 329, 357, 411, 442, 468, 496, 549, 609, 638, 664.
Loomis, Alfred L., the New York Academy of Medicine—what it is and what it may be, 153.
Loomis, Henry P., report of a case of general tuberculosis treated with Koch's lymph, with autopsy, 282.
Lowry, Agnes, purpura hæmorrhagica, 551.
Lunacy bill, the new, 295
Lunacy Commission, work of the, 263; report of the, 275.
Lunacy not increasing in New York State, 173.
Lundy, Charles J., hypodermic medication in diseases of the eye, 107.

Lupus, relationship of, to tuberculosis, 243; treatment of, by galvano-puncture, 426; treatment of, by Koch's method, 450, 493 *See* also inoculation experiments in tuberculosis; treatment of, by methylene, 737.
Lyle, Alexander, acquired syphilis in a child four years of age, probably as a result of rape, 158.
Lymph, animal *vs.* human, 240; Koch's, 84. *See* Inoculation experiments in tuberculosis; Koch's, and the coroner, 172.
Lymphadenitis, statistics of, 220.
Lymphangioma circumscriptum, 561.

M

McCabe, N., an apparent cure of acute pulmonary tuberculosis, 80.
McClure, W. J., death of, 141.
McDowell's method of controlling epistaxis, 81.
McFarland, W. C., death of, 332.
Macanley, Berkeley, a practical view of seasickness, 414.
Maghee, James M., abscess of the penis, complicating periurethritis, without perforation of the urethra, 622.
Magnetic healing, technique of, 144.
Maher, J. J. E., treatment of ingrowing toenail, 151.
Malaria and hepatic colic, relation between, 328; in New York, 381, 406; studies in, 579.
Malarial fever and eucalyptus drainage, 13; heart disease consequent on, 111.
Malays, black teeth of, 106.
Malpractice suit decided against the surgeon, 322.
Malthusianism, 407.
Mammary cancer, causes of, 211.
Mammen, E., nitrite of amyl in chloroform poisoning, 483; a case of laparotomy for tubo-ovarian disease, 678.
Manganese and gold, subcutaneous administration of, in the treatment of tuberculosis, 338, 354.
Manges, Morris, the quantitative estimation of sugar with Roberts' fermentation test, 505.
Mania, recurrent, 568.
Mann, F. P., advantages of combining iodine with glucose, 679.
Marine Hospital service, 142; new Surgeon-General of the, 713.
Marriage, the ideal Malthusian, 93.
Marriages, a study of consanguineous, 538.
Marshall, John, death of, 151.
Massachusetts, regulating the practice of medicine in, 436.
Massage in fractures, 234.
Mattison, Dr. J. B., hypnal, the new nervine, 8.
Maxilla, recurring luxation of, 298.
May, John Frederick, death of, 539.
"Medical and Surgical College of the State of New Jersey," resolutions of the Hudson County Medical Society concerning, 240.
Medical cannibalism *versus* professional honor and personal dignity, 273.
Medical co-education, 350.
Medical education, 236; an important reform in, 656; in England and America, comparative cost of, 517, 686.
Medical examinations in New York State, 600, 631.
Medical examiners, New York State Board of, 432, 433, 537.
Medical fellowships at Harvard, 687.
Medical jurisprudence, 159.
Medical legislation, activity in, 432; in Alabama, 463, 538; in Arkansas, 603; in France, 538; in New York in 1891, 582.
Medical men and the secular press, 467; in England, honors to, 121.
Medical practice, reciprocity in, 84*a*.
Medical profession in Japan, 598.
Medical Society of the County of New York, 140, 187, 269, 439, 467, 719; prize of the, 688.
Medical Society of the State of New York, 177.
Medical teaching, new era in, 173.
Medical women, ought they to marry? 711.
Medicine and money, 141; graduating age in, 378; should a poor man study, 169, 246, 301; the possibilities of, 333.
Medico-legal cases, 535, 674.
Meek, H., how Lawson Tait does a suprapubic cystotomy, 610.
Meierhof, E., a hook for the removal of foreign bodies from the ear, 528.
Melancholia, cured by trachelorrhaphy, 135; forms of, 178.
Membrana tympani, perforation of, 385; spurious, 623.
Meningitis, cerebro-spinal, in an infant, due to the diplococcus pneumoniæ of Fraenkel and Weichselbaum, 43, 64; epidemic cerebro-spinal, 578; micro-organisms in, 536; tubercular, following operation for osteitis of the shoulder, 272.
Menorrhagia and metrorrhagia, treatment of, by the chemico-galvano-caustic action of the positive pole, 216, 366.
Menstrual epoch, management of the, 12.
Menstruation, and ovulation, 579; in men, 212.
Mental development, defective, linear craniotomy, 607.
Mercury, absorption of, by a tape-worm, 472.
Methyl blue in diphtheria, 356; in therapeutics, 52, 240, 301, 358, 404, 473.
Methylene in the treatment of lupus, 737.
Metrorrhagia and menorrhagia, treatment of, by the chemical galvano-caustic action of the positive pole, 366.
Meyer, Willy, notes on the effect of the aniline dyes, especially the blue pyoktanin, in the treatment of inoperable malignant growths, 473; the treatment of inoperable malignant growths by the aniline dyes, 301.
Microcephalus, craniectomy for, 232.
Microcidine, 603.
Micro-organisms, action of infusion of coffee on, 360; action of living blood in, 14; and specifics, 206; (diplococcus pneumoniæ) in a case of cerebro-spinal meningitis in an infant, 43, 64; grouping of, 371; in cancer, 20, 429; in diphtheria, 484; in great cities, 191; in meningitis, 536; in syphilis, 575; industrial use of, 220; literature of, 192; typhoid and pseudo-typhoid, in river-water, 484.
Microscope lenses, improvement in, 604.
Middletown insane asylum, 265.
Milhau, John Jefferson, obituary of, 576.
Milk, blue, 205; fetid, in human mammary glands, 569; human, pathological variations of, 18; of the Egyptian buffalo, 188; predigested, sterilization of, 264; secretion of, in the new-born, 262; sterilization of, 608; sterilized, 409; sterilizing by peroxide of hydrogen, 276; sugarless, 631; tuberculous, experimental investigations with, 203.
Milk-diet, in scurvy, 286; overdone in typhoid fever, 373.

Milliken, S. E., the treatment of hernia by means of the hank truss, 616, 636.
Mineral springs, resources of American, 507.
Miracle, cure by, 598.
Miscarriage, retained placenta in, 581.

New York State, charities of, 212; Medical Library of, 240, 433.
New York State Medical Association, Fifth District Branch, 715.
Nicaragua Canal Company's Hospital at Greytown, 53.
Nicholas, G. L., bacteriological report on a case of anthrax, 597.
Nomenclature, personal, in medicine, 290.
Nose and throat, experience with trichloracetic acid in two hundred cases of affections of the, 312; local treatment of diseases of, 422, 439.
Nose, a hair-pin in the, 729; congenital median furrow of the, 117; foreign bodies in the, pneumatic method of removing, 93; red, treatment of, 352.
"Not so bad as it seems," 443.
Noyes, Henry D., hemianopsia, 389.
Nurse, excessive punishment of a, for striking a patient, 656; the male, 655.
Nurses, registration of, in England, 189.
Nussbaum, a memorial to the late Professor, 686.

O

Oatman, E. L., aseptic tongue spatula, 311.
Obstetrical atmospheric tractor, 385.
Obstetrics, clinical teaching of, in America, 548; in the West, Winckel on, 20; statistics of, 630.
Obstruction, intestinal, 83.
O'Callaghan, T. A., post-mortem Cæsarean section, 513.
O'Dwyer's views on intubation, 696.
Œdema, acute circumscribed, 559.
Œsophagus, stricture of, loss of tube in, 383; stricture of, treatment by linear electrolysis, 14; varicose ulcer of the, 262.
Ogden Fred. N., hot dilute sulphurous acid in the treatment of diphtheria, 402.
O'Hanlon, Philip F., a complaint against the undertaker, 92.
Ointments, absorption of drugs in the form of, 283.
Old age, frequency of perforation and peritonitis from gall-stones in, 327; in California, 170; leprosy in, 176; points to be observed by elderly men, 14.
Olive-oil in the treatment of gall-stones, 693.
Operating, the time of day for, 54.
Operation, minor, death after a, 721.
Operations, amphitheatre, 77; curative effect of, *per se*, 636.
Ophthalmia, sympathetic, management of, 321; sympathetic, preventive treatment of, 235.
Ophthalmic artery, aneurism of the, ligature of the carotid for, 78.
Opiates in acute peritonitis, 613.
Opium, defending the use of, 683; habitués, a home for, 658; traffic in India, 497.
Orbital neuritis, 89.
Orexin, experiments with, 13.
Osteitis of the shoulder, tubercular meningitis following operation for, 272; tubercular, of the femur, 272.
Otitis, chronic purulent, 465; early treatment of, 189; media, abscess of the temporo-sphenoidal lobe secondary to, 183.
Ovarian disease, laparotomy for, 678.
Ovaritis, chronic, pathology and treatment of, 663.
Ovary, papilloma of the, developing soon after laparotomy, 215.
Overall, G. M., painless circumcision, 78.
Ovulation and menstruation, 579.
Owings, John H., separation of the condyloid epiphysis of the femur, 11.
Oxalemia, 206.
Oxaluria, 49.
Oxygen, hypodermic injection of, 84 *c*; inhalations of, in defective arterialization, 78; inhalations of, relief of heart-disease with pulmonary œdema by, 483.

P

Pachymeningitis hæmorrhagica, 441; interna, 64.
Pahl, B. M., death of, 379.
Pain, relief of pelvic and abdominal, by hot colon douches, 592.
Palpitation, cold applications for the relief of, 204.
Pan-American Medical Congress, 460, 573.
Papillitis, 89.
Papilloma of the ovary developing soon after laparotomy, 215.
Paquelin cautery, how to keep in good order, 248.
Paralysis, acute ascending, 226; for hypodermic injection of ether, 266; periodic, 525; traumatic, of the abducent and oculo-motor nerves, 402.
Paranoia recurrens, 568.
Parataloid, 142; injections of, see Inoculation experiments for tuberculosis.
Paris, practitioners in, 435.
Parker, Charles T., death of, 408.
Parrish, Joseph, death of, 141.
Parturition, unconscious, 144.
Patella, luxation of, 298.
Patent medicines and food products, American, in Europe, 536.
Patents for dental work, 92.
Pathologist, the day of the, 628.
Peck, F. H., practical notes on the prophylaxis and treatment of diphtheria, 136.
Pelvic and rectal diseases in woman, association of, 721.
Pelvic disease, relation to displacement of the abdominal viscera to, 636.
Pelvic inflammation in women, 180; joint reflexes following, 548.
Pelvis, elevation of, in abdominal section, 137.
Penis, abscess of the, complicating periurethritis, without perforation of the urethra, 622; percussion reflex of the, 115.
Pennsylvania pharmacy law, 471.
Peppermint oil in the treatment of grip, 483.
Pericardium, tuberculosis of the, 63.
Perineal structures, restoration of the, 662.
Perineorrhaphy, 193, 213.
Perineum, location of the, 353.
Periodic paralysis, 525.
Peristalsis, observations on, 372.
Peritoneal section, comparative study of one hundred and fifty-nine cases, 533.
Peritonitis, acute, opiates in, 613; acute general suppurative, operative procedures in, 178; experimental, 286-680; from a surgical stand-point, 605; opiates in the treatment of, 613, 716; tubercular, exploratory laparotomy in, 466.
Permanganate of potassium in bites from poisonous insects, 36, 274; in diphtheria, 682.
Peroxide of hydrogen as a disinfectant, 439; preservation of, 569; sterilizing milk by, 276.
Perry, Gideon B., death of, 53.
Personal nomenclature of disease, 319.
Pertussis, treatment of, by atomization, 676.
Pes planus, 137.
Peterson, Frederick, a further study of anodal diffusion as a therapeutic agent, 133.
Phagocytosis and immunity, 484.
Pharyngeal and faucial tenesmus, 204.
Pharyngitis and gastritis, mental relations of, 674.
Phelps, A. M., a new artery forceps, 498; transplantation of tissue from lower animals to man; and a report of the case of bone-transplantation at Charity Hospital, Blackwell's Island, N. Y. 221.
Phillips, Wendell C. some points on the local therapeutics of diseases of the nose and throat, 422, 439.
Phonograph and micro-graphophone in medical and other sciences, 526, 697.
Phtheiriasis, quassia for, 49; remedy for, 351.
Phthisis, pronunciation of the word, 322; pulmonalis, and the bacillus, 237; cantharidin as the theoretically ideal remedy for, 596; its classification, early diagnosis, and relations to chronic pneumonia, 185; prophylaxis of, 580, 627; treatment of, by Koch's method, *see* in-

oculation experiments in tuberculosis; treatment of, by compressed air and creasote, 687; treatment of, by transfusion, 322; treatment of high temperature in, by small and frequently repeated doses of antifebrin, 428.
Physician, the working, a vital question for, 91.
Physicians' Mutual Aid Association, 142;
Physicians' mutual protective associations, 113.
Pigmentation, brown, from arsenic, 262; in pregnant women, treatment of, 556.
Pilocarpine in pneumonia, 652.
Pisko, Edward, the "potato cure" for foreign bodies in the stomach, 11.
Placenta, retained, in miscarriage, 581; white infarct of the, 681.
Placenta prævia centralis with transverse presentation, 81.
Placentitis, interstitial, 709.
Platinum instruments, use of, in the extraction of cataract, etc., 179.
Pleura, calcareous degeneration of the, 289; endothelioma of the, 271.
Pleuritic adhesions, frequency of, 293.
Pleuritis, circumscribed, frequent localization of, beneath the scapulæ, 417.
Pneumococcus, antagonism of, to the tubercle bacillus, 695.
Pneumonia, abortion of, 512, 665; an epidemic of, 653; calomel in, 653; lobar, with the production of connective tissue in the air-spaces, 181; pilocarpine in, 652; the blood in, 524; the diagnostic value of vocal fremitus in, 643, 723; treatment of, 348, 580; treatment of the first stage of, 577.
Poisoning by aconite, a case of, 521; by salol, 687; imaginary, 654; wholesale, of a wedding party, 574.
Poison-proof animals, 470.
Poisonous insects, permanganate of potassium in bites from, 36.
Politzerization, 287.
Polyclinic, a private, in Berlin, 630.
Poor man, should a, study medicine, 169, 246, 301.
Porcher, F. Peyre, the epidemic of la grippe, 444.
Pork, eating of, and cancer, 246; examination of salted, 18.
Portugal, medical teaching in, 141.
Post, Sarah E., a case of hysterical aorta, 455.
Post-Graduate Medical School, annual dinner of the, 573; in Brooklyn, 53.
Post-partum hemorrhage, hypodermic injections of caffeine in, 13; treatment of acute anæmia after, by intra-venous saline injection, 703.
Potato treatment of foreign bodies in the stomach, 11, 218.
Pott's disease, necrosis of the ribs complicating, 178.
Powder-marks, absence of, no evidence against suicide, 36.
Powers, Charles A., a modified interdental pry, 274.
Practitioners' Society of New York, 117, 213, 326, 437, 465.
Præ-dormitium, sensory shocks of the, 17.
Pratt, Ambrose, death of, 713.
Preaching and practice, 172.
Pregnancy, Bright's disease of, 1; duration of, 373; extra-uterine, 662; extra-uterine, treatment of, 629; is the urine poisonous during? 302; vesical hemorrhage in, 309; vomiting of, 673.
Pregnant women, treatment of pigmentation in, 556.
Prescriptions, percentages on, 656; ownership of, 515.
Presentations, posterior face, treatment of, 664.
President, the, and the Queen, 571.
Press, secular, medical men and the, 467.
Prettyman, J. S., the rheumatoid condition, 649; tuberculosis is incurable, 218.
Preventive medicine, an institute of, 293, 380.
Prison labor, 159.
Prize of the Medical Society of the County of New York, 688; of the Paris Academy of Medicine, 53; the John Parkin, of the Royal College of Physicians of Edinburgh, 408; the Ricard, 142, 239; the Warren triennial, 212.
Probe, a telephonic, improvised from the telephone receiver, 61.
Proben, Charles J., placenta prævia centralis with transverse presentation, 81.
Professions, the, and idiocy, 113.
Progressive muscular atrophy, acute, 708.
Prostate, and seminal vesicle, tuberculosis of the, 411; removal of the hypertrophied median lobe of the, 297.
Prostatitis, acute, and prostatic abscess, 715.
Prostitution, protest against licensed, 729; regulation of, 375.
Prudden, T. Mitchell, cerebro-spinal meningitis in an infant due to the diplococcus pneumoniæ of Fraenkel and Weichselbaum, 43, 64; studies in the etiology of diphtheria—second series, 445.
Prussic acid, action of, in pulmonary tuberculosis, 568.
Pruyn, Peter V. S., obituary of, 576.
Pseudo-leukæmia, 63.
Psoriasis, syphilitic palmar, treatment of, 597.
Psorospermosis, 206.
Psorosperms in cancer, 303.
Pterygium, extreme cases of, 536.
Puberty, barking cough of, 138.
Puerperal convulsions, prevention of, by induction of premature delivery, 547.
Puerperal fever, tape-worm as a cause of, 176.
Puerperal period, the emotional element in, 181.
Pulse-rate, annual variations of the, 713.
Purpura hæmorrhagica, 155, 551; rheumatica, 15.
Pus-corpuscles, structure of, 272.
Pylorectomy with gastro-enterostomy, 39.
Pyoktanin in foot-and-mouth disease, 683; in therapeutics, 52, 240, 301, 358, 404, 473; to remove the stains of, from the hands, 472.

Q

Quack, misfortunes of a, 173.
Quack remedies, religious advertising of, 276.
Quackery, temptations to, 696.
Quarantine, at New York, 350; at Philadelphia not to be moved, 176.
Quassia for phtheiriasis, 49.
Queen, the, and the President, 571.
Quimby, C. E., the treatment of pulmonary tuberculosis by Koch's method, 73.
Quinine, a new substitute for, 599; and hæmoglobinuria, 388; artificial, 631; to disguise the taste of, 205.
Quinlan, Francis J., a case of convergent squint corrected by Adam's modified operation for deflected septum, 617.
Quintard, Edward, the Transfiguration clinic, 66.

R

Rabies, a case of, 521; deaths from, 276; discussion on, 29; paralytic, supposed death from, 265; the clinical aspect of, 6; the reality of, 3.
Rachitis, treatment of, 737.
Racial immunity and inoculation, 67.
Radius, refracture of the, 298.
Railway sanitation, 141.
Railway surgeons, question as to the ethical standing of, 542.
Railway surgery, 177.
Rand, J. P., the diagnostic value of vocal fremitus in pneumonia, 643.

Ransom, W. J., apomorphine as an antidote for poisoning by strychnine, 79; essential hydrops, 79.
Rectal and pelvic diseases in woman, association of, 721.
Rector, Pierson, death of, 142.
Rectum, carcinoma of, extirpation of, in two sittings, 206; stricture of the, 543.
Reflexes, joint, consecutive to pelvic inflammation, 548; penis percussion, 115.
Respiration, forced, 545.
Respiratory movements and the anatomy of the thorax, 437.
Retinol, properties of, 287.
Reunion of severed parts, 93.
Review, an interesting, 113.
Reyher, Charles, death of, 435.
Rheumatic and rheumatoid arthritis, 139.
Rheumatoid condition, the, 649.
Rhinitis, chronic atrophic, cured by inoculation with gonorrhœal pus, 497.
Ribs, necrosis of, complicating Pott's disease, 178.
Rice, Clarence C., lupus of the nose and throat—demonstration of cases under the Koch method of treatment, 450; the etiology of the disease known as suppurative tonsillitis and its surgical treatment, with remarks concerning the prevention of inflammatory disorders of the tonsils, 125.
Ridlon, John, the non-operative treatment of delayed union in fractures of the leg, 130.
Riley, Henry A., interesting medical cases, 535; medical jurisprudence, 159; notes in medical jurisprudence, 346; recent cases in the courts, 674.
Ringworm, treatment of, 204.
Roberts' fermentation test for the quantitative estimation of sugar, 505.
Roberts, Walter T., gangrene of the skin in an infant, 426.
Rockwell, A. D., the different physiological and therapeutical properties of the induced currents of electricity, with special reference to bipolar faradization, 187, 201.
Rodgers, Harris C., a definition of insanity, 360.
Roskoten, Oliver J., aborting pneumonia, 512.
von Ruck, Karl, a contribution to the clinical uses of Professor Koch's remedy for tuberculosis, 589; delayed reaction from lymph, 143.
Russia, adoption of the decimal system in, 559; homœopathy in, 144.
Ryerson, G. Sterling, extreme cases of pterygium, 536.

S

St. Petersburg, insalubrious condition of, 472.
Salicylates and iodine, antagonism between, as regards exudations and transudations, 206.
Salicylic acid for corns, 49.
Salol as an antiseptic in cancer of the uterus, 525; death after a dose of, 687; in enteric fever, 266; in typhoid fever, 612.
Salpingitis, gonorrhœal, 234.
Salpingocele, femoral, 12.
Sanitation, in the West, 539; railway, 141; ship, 696.
Sanity and insanity, signs of, 208.
Santoninoxime, 332; as a vermifuge, 205.
Saphena vein, ligature of, in cases of varicose veins, 567.
Sarcoma, colloid, weighing thirty pounds, 384; melanotic, of the choroid, 478; of the knee, 495.
Scarlet fever, immunity of the Japanese from, 527.
Scarlatina, in Japan, 358; the fever in, 36; the tongue in, 569; without pyrexia, 204.
Schmid, H. Ernest, treatment of whooping-cough by atomization, 676.
Schools, contagious diseases in, 292; in tenement houses, 66; public, hygiene of, 211.
Schott, Theodor, balneo-therapeutics and mechano-therapeutics applied to the treatment of chronic heart disease, 198.

de Schweinitz, G. E., a case of persisting hemorrhage from the conjunctiva of a new-born infant, following the instillation of a solution of nitrate of silver, 456.
Sciatica, traumatic, cured by removal of a spiculum of bone from the edge of the great sacro-sciatic foramen, 82.
Scrofuloderma, 288.
Scurvy, milk diet in, 286.
Sea-air, salts of the, 680.
Sea-sickness, 15; practical view of, 414.
Semen, microscopical examination of, 317.
Semilunar ganglia, removal of, through the floor of the cranium, 606.
Sensory derangements following intra-cerebral injuries, 419.
Sensory shocks of the præ-dormitium, 17.
Septum, deflected nasal, convergent squint corrected by Adam's modified operation for, 617.
Setons and issues, 457.
Sexes, co-education of the, 19, 53.
Sexton, Samuel, some remarks on the early treatment of otitis, 189.
Sexual education for the young, 497.
Sexual function, some facts about the, 570.
Sexual perversion, 629.
Sexual precocity, 574.
Ship sanitation, needed improvement in, 696.
Shock, 509.
Shoulder-cap and elbow splint combined, 10.
Shoulder-joints, simultaneous dislocation of both, 36.
Siegfried, C. A., studies on the influenza as occurring in Russia, 531.
Sinkler, Wharton, sulphate of cinchonidine in intermittent fever, 246.
Sinus, lateral, thrombosis of the, 465.
Sinuses, formation, structure, function, and pathology of, 254.
Skin, annual shedding of the, 212; transplantation of, the finger as a medium for, 117.
Skin-grafting, Thiersch's, 383.
Skull, fracture of the base of the, causing total paralysis of both sixth cranial nerves and partial paralysis of the sensory roots of both fifth cranial nerves, 617.
Sleep, sensory shocks preceding loss of consciousness in, 17.
Slocum, Charles E., an old surgical bill, 218, 295.
Small, J. W., abortion of pneumonia, 665.
Small-pox, cocaine in, 500.
Smith, Andrew H., is parataloid of uniform strength? 247; relation between the amount of tuberculous tissue and dose of the lymph in the Koch treatment, 192.
Smith, Frank Fremont, the latest development of the lymph treatment in Berlin, 27.
Smith, George K., the treatment of herpes zoster, 426.
Smith, Gouverneur M., an international congress of microbes at Berlin, 68.
Smith, Joseph T., diabetes mellitus, 481.
Smith, Stephen, opiates in acute peritonitis, 613, 716.
Smith, William M., variola on the Scotia, 610.
Snake bite, cure of, by injection of mongoose blood, 683; strychnine in, 683.
Snare nasal, modification of a, 724.
Society of the Alumni of Bellevue Hospital, 573.
Sore-throat, hot claret as a gargle in, 355.
Spatula, aseptic tongue, 311.
Specialism, Dr. Holmes on, 303.
Speculum, self retaining vaginal, for operations in the dorsal position, 283.
Spinal cord disease, a new type of, 516.
Spinal hemorrhage, idiopathic, 651.
Spine, posterior rachitic curvature of the, 9; results obtained by the application of heat and cold to the, 269.
Spleen, abscess of the, 579; enlarged, local treatment of, 168; fatal rupture of the, 416; removal of, after gunshot wound, 383.
Sprague, W. B., death of, 378.
Sprains, treatment of, 607, 625.
Spratling, W. P., aural hallucinations cured by removal of foreign bodies from the ear, 680; should a poor man study medicine, 246.
Squint, convergent, corrected by Adam's modified operation for deflected septum, 617.
Squire, C. L., rupture of the right ventricle, death in twenty-five hours—autopsy, 621.
Stanton, Joshua Otis, death of, 461.
Staphylorrhaphy needle, a new, 387.
Stark, Henry S., acute anterior gonorrhœa, the indications for, and rational methods of, treatment, 161.
Sterilization of milk, 608.
Sterling, Elisha, death of, 240.
Stevens, Henry W., death of, 265.
Stickler, Joseph William, a consideration of Professor Koch's method of treating pulmonary tuberculosis; some of the complications apt to arise, some of the dangers to be apprehended, 44.
Stigmata, neurasthenic, 487.
Stimulants, need of stronger, 490.
Stocking, S., death of, 659.
Stomach, cancer of, the gastric functions in, 288; cancer of the pylorus, operations for, 37, 39, 62; new method for the direct electrization of the, 529; persistent reflux of bile into the, 274; relation of disorders of the, to affections of the male genital organs, 484; why self-digestion does not occur, 289.
Stomach-washing in very young children, 205.
Stone in the bladder, some sources of error in sounding for, 111.
Stricture, intestinal, secondary to strangulation in a hernial sac, 497; rectal, 543; spasmodic, of the female urethra following labor, 547; traumatic resection of the urethra for, 220; urethral, rapid dilatation for, 178; urethral, treatment of, 582; urethral, the treatment of, and a new divulsor for rapid dilatation, 645; urethral, treatment of, by linear electrolysis, 14; urethral, treatment of organic, 625.
Strychnine in the treatment of chronic alcoholism, 548; in the treatment of snake-bite, 683; poisoning by, apomorphine as an antidote in, 79.
Study, Joseph N., appendicitis—death in forty-two hours, 166.
Subclavian artery, aneurism of the first two portions of the, operative surgical treatment for, 305, 325.
Sugar in the blood, amount of, in disease, 13; quantitative estimation of, with Roberts' fermentation test, 505.
Suicide, absence of powder marks no evidence against, 36; among school-children in Prussia, 35.
Sulphonal in psychoses, 377.
Sulphurous acid, hot dilute, in the treatment of diphtheria, 402.
Supreme court dicision of interest to physicians, 730.
"Sweating system" in medical practice, 572.
Sweet oil in the treatment of gall-stones, 16.
Sylvester, F. E., a new ligature box, 122.
Sympathetic ophthalmia, management of, 321.
Symptoms, can we complain of? 571.
Syphilis, abortive treatment of, 685; acquired, in a child four years of age, probably as a result of rape, 158; and dentistry, 570; bacilli in, 575; injection treatment of, 112, 597; not of American origin, 683; of the lungs, 682.
Syphilitic anæmia, 211.
Syria, cholera in, 210.

T

Tabes, an early symptom of, 428; some practical points in the diagnosis of, 424.
Tait, Lawson, on the remote effects of removal of the uterine appendages, 501.
Talcott, Alvan, death of, 416.
Talmud, bacilli in the, 164.
Tampons, vaginal, 663.
Tape-worm, absorption of mercury by a, 472; as a cause of puerperal fever, 176.
Taylor, R. W., chancres of the fingers, their clinical history, their complicating septic infections, and their danger in surgical and obstetrical practice, 69.
Taylor, Wallace, cancer of the cervix uteri with co-existing pregnancy — vaginal hysterectomy—recovery, 259.
Teeth, black, of Malays, 106.
Telephonic probe improvised from the telephone receiver, 61.
Temperance, medical men and, 527.
Temperature, an unusually high, in a child, 553; influence of, upon mortality, 320; reduction of, by the ice-cradle, 294.
Tendon, gangrene of a, 568.
Tenement-house schools, 66.
Tennessee State Medical Society, fifty-eighth annual meeting, 579.
Tetanie or anthrogryposis, 276.
Tetanus neonatorum, 662.
Tetanus, of the uterus, treated with antipyrin, 206; poison of, 291; traumatic, 79.
Tetronal, 114.
Thacher, James Kingsley, obituary of, 492.
Therapeutics, rational, 557; renaissance of, 471.
Thomas, Hugh Owen, obituary of, 60.
Thomas, John J., an improved instrument for administering hypodermic injections, 190.
Thomas, T. Gaillard, obituary of Coert Dubois, M.D., 60; the possibilities of medicine, 333.
Thompson, J. M., more about the dispensaries, 301.
Thompson, William S., death of, 659.
Thorax, traumatism of the, 605.
Throat and nose, experience with trichloracetic acid in two hundred cases of affections of, 312.
Throat clinics in Vienna, 217.
Thrombosis of the lateral sinus, 465.
Thyroid grafting in myxœdema, 13, 235, 601, 625.
